The Python Library Reference

Release 3.13.4

Guido van Rossum and the Python development team

June 03, 2025

Python Software Foundation
Email: docs@python.org

CONTENTS

1 Introduction **3**
- 1.1 Notes on availability . . . 3
  - 1.1.1 WebAssembly platforms . . . 4
  - 1.1.2 Mobile platforms . . . 4

2 Built-in Functions **7**

3 Built-in Constants **35**
- 3.1 Constants added by the `site` module . . . 36

4 Built-in Types **37**
- 4.1 Truth Value Testing . . . 37
- 4.2 Boolean Operations — `and`, `or`, `not` . . . 37
- 4.3 Comparisons . . . 38
- 4.4 Numeric Types — `int`, `float`, `complex` . . . 38
  - 4.4.1 Bitwise Operations on Integer Types . . . 40
  - 4.4.2 Additional Methods on Integer Types . . . 40
  - 4.4.3 Additional Methods on Float . . . 42
  - 4.4.4 Hashing of numeric types . . . 43
- 4.5 Boolean Type - `bool` . . . 45
- 4.6 Iterator Types . . . 45
  - 4.6.1 Generator Types . . . 46
- 4.7 Sequence Types — `list`, `tuple`, `range` . . . 46
  - 4.7.1 Common Sequence Operations . . . 46
  - 4.7.2 Immutable Sequence Types . . . 48
  - 4.7.3 Mutable Sequence Types . . . 48
  - 4.7.4 Lists . . . 49
  - 4.7.5 Tuples . . . 49
  - 4.7.6 Ranges . . . 50
- 4.8 Text Sequence Type — `str` . . . 51
  - 4.8.1 String Methods . . . 52
  - 4.8.2 Formatted String Literals (f-strings) . . . 61
  - 4.8.3 `printf`-style String Formatting . . . 63
- 4.9 Binary Sequence Types — `bytes`, `bytearray`, `memoryview` . . . 65
  - 4.9.1 Bytes Objects . . . 65
  - 4.9.2 Bytearray Objects . . . 66
  - 4.9.3 Bytes and Bytearray Operations . . . 67
  - 4.9.4 `printf`-style Bytes Formatting . . . 78
  - 4.9.5 Memory Views . . . 80
- 4.10 Set Types — `set`, `frozenset` . . . 87
- 4.11 Mapping Types — `dict` . . . 89
  - 4.11.1 Dictionary view objects . . . 93
- 4.12 Context Manager Types . . . 94
- 4.13 Type Annotation Types — Generic Alias, Union . . . 95

4.13.1 Generic Alias Type . . . 95
4.13.2 Union Type . . . 99
4.14 Other Built-in Types . . . 101
4.14.1 Modules . . . 101
4.14.2 Classes and Class Instances . . . 101
4.14.3 Functions . . . 101
4.14.4 Methods . . . 101
4.14.5 Code Objects . . . 102
4.14.6 Type Objects . . . 102
4.14.7 The Null Object . . . 102
4.14.8 The Ellipsis Object . . . 102
4.14.9 The NotImplemented Object . . . 102
4.14.10 Internal Objects . . . 102
4.15 Special Attributes . . . 103
4.16 Integer string conversion length limitation . . . 103
4.16.1 Affected APIs . . . 104
4.16.2 Configuring the limit . . . 104
4.16.3 Recommended configuration . . . 105

5 Built-in Exceptions **107**
5.1 Exception context . . . 107
5.2 Inheriting from built-in exceptions . . . 108
5.3 Base classes . . . 108
5.4 Concrete exceptions . . . 109
5.4.1 OS exceptions . . . 114
5.5 Warnings . . . 115
5.6 Exception groups . . . 116
5.7 Exception hierarchy . . . 118

6 Text Processing Services **121**
6.1 `string` — Common string operations . . . 121
6.1.1 String constants . . . 121
6.1.2 Custom String Formatting . . . 122
6.1.3 Format String Syntax . . . 123
6.1.4 Template strings . . . 130
6.1.5 Helper functions . . . 132
6.2 `re` — Regular expression operations . . . 132
6.2.1 Regular Expression Syntax . . . 133
6.2.2 Module Contents . . . 140
6.2.3 Regular Expression Objects . . . 146
6.2.4 Match Objects . . . 147
6.2.5 Regular Expression Examples . . . 150
6.3 `difflib` — Helpers for computing deltas . . . 155
6.3.1 SequenceMatcher Objects . . . 159
6.3.2 SequenceMatcher Examples . . . 162
6.3.3 Differ Objects . . . 163
6.3.4 Differ Example . . . 163
6.3.5 A command-line interface to difflib . . . 164
6.3.6 ndiff example . . . 165
6.4 `textwrap` — Text wrapping and filling . . . 168
6.5 `unicodedata` — Unicode Database . . . 171
6.6 `stringprep` — Internet String Preparation . . . 173
6.7 `readline` — GNU readline interface . . . 174
6.7.1 Init file . . . 175
6.7.2 Line buffer . . . 175
6.7.3 History file . . . 175
6.7.4 History list . . . 176
6.7.5 Startup hooks . . . 176

6.7.6 Completion . . . 177
6.7.7 Example . . . 177
6.8 rlcompleter — Completion function for GNU readline . . . 179

7 Binary Data Services **181**
7.1 struct — Interpret bytes as packed binary data . . . 181
7.1.1 Functions and Exceptions . . . 181
7.1.2 Format Strings . . . 182
7.1.3 Applications . . . 186
7.1.4 Classes . . . 187
7.2 codecs — Codec registry and base classes . . . 188
7.2.1 Codec Base Classes . . . 191
7.2.2 Encodings and Unicode . . . 197
7.2.3 Standard Encodings . . . 199
7.2.4 Python Specific Encodings . . . 201
7.2.5 encodings.idna — Internationalized Domain Names in Applications . . . 203
7.2.6 encodings.mbcs — Windows ANSI codepage . . . 204
7.2.7 encodings.utf_8_sig — UTF-8 codec with BOM signature . . . 204

8 Data Types **205**
8.1 datetime — Basic date and time types . . . 205
8.1.1 Aware and Naive Objects . . . 205
8.1.2 Constants . . . 206
8.1.3 Available Types . . . 206
8.1.4 timedelta Objects . . . 207
8.1.5 date Objects . . . 211
8.1.6 datetime Objects . . . 216
8.1.7 time Objects . . . 227
8.1.8 tzinfo Objects . . . 231
8.1.9 timezone Objects . . . 237
8.1.10 strftime() and strptime() Behavior . . . 238
8.2 zoneinfo — IANA time zone support . . . 243
8.2.1 Using ZoneInfo . . . 243
8.2.2 Data sources . . . 244
8.2.3 The ZoneInfo class . . . 245
8.2.4 Functions . . . 247
8.2.5 Globals . . . 247
8.2.6 Exceptions and warnings . . . 248
8.3 calendar — General calendar-related functions . . . 248
8.3.1 Command-Line Usage . . . 254
8.4 collections — Container datatypes . . . 256
8.4.1 ChainMap objects . . . 256
8.4.2 Counter objects . . . 258
8.4.3 deque objects . . . 262
8.4.4 defaultdict objects . . . 265
8.4.5 namedtuple() Factory Function for Tuples with Named Fields . . . 267
8.4.6 OrderedDict objects . . . 270
8.4.7 UserDict objects . . . 272
8.4.8 UserList objects . . . 273
8.4.9 UserString objects . . . 273
8.5 collections.abc — Abstract Base Classes for Containers . . . 273
8.5.1 Collections Abstract Base Classes . . . 275
8.5.2 Collections Abstract Base Classes – Detailed Descriptions . . . 277
8.5.3 Examples and Recipes . . . 279
8.6 heapq — Heap queue algorithm . . . 280
8.6.1 Basic Examples . . . 281
8.6.2 Priority Queue Implementation Notes . . . 281
8.6.3 Theory . . . 282

8.7 bisect — Array bisection algorithm . . . 283
8.7.1 Performance Notes . . . 285
8.7.2 Searching Sorted Lists . . . 285
8.7.3 Examples . . . 286
8.8 array — Efficient arrays of numeric values . . . 287
8.9 weakref — Weak references . . . 290
8.9.1 Weak Reference Objects . . . 294
8.9.2 Example . . . 295
8.9.3 Finalizer Objects . . . 295
8.9.4 Comparing finalizers with __del__() methods . . . 296
8.10 types — Dynamic type creation and names for built-in types . . . 297
8.10.1 Dynamic Type Creation . . . 298
8.10.2 Standard Interpreter Types . . . 299
8.10.3 Additional Utility Classes and Functions . . . 303
8.10.4 Coroutine Utility Functions . . . 303
8.11 copy — Shallow and deep copy operations . . . 304
8.12 pprint — Data pretty printer . . . 305
8.12.1 Functions . . . 305
8.12.2 PrettyPrinter Objects . . . 306
8.12.3 Example . . . 308
8.13 reprlib — Alternate repr() implementation . . . 311
8.13.1 Repr Objects . . . 312
8.13.2 Subclassing Repr Objects . . . 313
8.14 enum — Support for enumerations . . . 314
8.14.1 Module Contents . . . 315
8.14.2 Data Types . . . 316
8.14.3 Utilities and Decorators . . . 327
8.14.4 Notes . . . 329
8.15 graphlib — Functionality to operate with graph-like structures . . . 329
8.15.1 Exceptions . . . 331

9 Numeric and Mathematical Modules 333
9.1 numbers — Numeric abstract base classes . . . 333
9.1.1 The numeric tower . . . 333
9.1.2 Notes for type implementers . . . 334
9.2 math — Mathematical functions . . . 336
9.2.1 Number-theoretic functions . . . 337
9.2.2 Floating point arithmetic . . . 338
9.2.3 Floating point manipulation functions . . . 339
9.2.4 Power, exponential and logarithmic functions . . . 341
9.2.5 Summation and product functions . . . 342
9.2.6 Angular conversion . . . 343
9.2.7 Trigonometric functions . . . 343
9.2.8 Hyperbolic functions . . . 343
9.2.9 Special functions . . . 344
9.2.10 Constants . . . 344
9.3 cmath — Mathematical functions for complex numbers . . . 345
9.3.1 Conversions to and from polar coordinates . . . 346
9.3.2 Power and logarithmic functions . . . 347
9.3.3 Trigonometric functions . . . 347
9.3.4 Hyperbolic functions . . . 348
9.3.5 Classification functions . . . 348
9.3.6 Constants . . . 349
9.4 decimal — Decimal fixed-point and floating-point arithmetic . . . 349
9.4.1 Quick-start tutorial . . . 351
9.4.2 Decimal objects . . . 354
9.4.3 Context objects . . . 361
9.4.4 Constants . . . 368

9.4.5 Rounding modes . . . 368
9.4.6 Signals . . . 369
9.4.7 Floating-point notes . . . 370
9.4.8 Working with threads . . . 372
9.4.9 Recipes . . . 372
9.4.10 Decimal FAQ . . . 375
9.5 fractions — Rational numbers . . . 378
9.6 random — Generate pseudo-random numbers . . . 381
9.6.1 Bookkeeping functions . . . 382
9.6.2 Functions for bytes . . . 382
9.6.3 Functions for integers . . . 383
9.6.4 Functions for sequences . . . 383
9.6.5 Discrete distributions . . . 384
9.6.6 Real-valued distributions . . . 384
9.6.7 Alternative Generator . . . 386
9.6.8 Notes on Reproducibility . . . 386
9.6.9 Examples . . . 386
9.6.10 Recipes . . . 389
9.6.11 Command-line usage . . . 390
9.6.12 Command-line example . . . 390
9.7 statistics — Mathematical statistics functions . . . 391
9.7.1 Averages and measures of central location . . . 392
9.7.2 Measures of spread . . . 392
9.7.3 Statistics for relations between two inputs . . . 392
9.7.4 Function details . . . 392
9.7.5 Exceptions . . . 402
9.7.6 NormalDist objects . . . 402
9.7.7 Examples and Recipes . . . 404

10 Functional Programming Modules **407**
10.1 itertools — Functions creating iterators for efficient looping . . . 407
10.1.1 Itertool Functions . . . 409
10.1.2 Itertools Recipes . . . 419
10.2 functools — Higher-order functions and operations on callable objects . . . 424
10.2.1 partial Objects . . . 434
10.3 operator — Standard operators as functions . . . 435
10.3.1 Mapping Operators to Functions . . . 439
10.3.2 In-place Operators . . . 440

11 File and Directory Access **443**
11.1 pathlib — Object-oriented filesystem paths . . . 443
11.1.1 Basic use . . . 444
11.1.2 Exceptions . . . 445
11.1.3 Pure paths . . . 445
11.1.4 Concrete paths . . . 454
11.1.5 Pattern language . . . 465
11.1.6 Comparison to the glob module . . . 466
11.1.7 Comparison to the os and os.path modules . . . 466
11.2 os.path — Common pathname manipulations . . . 468
11.3 stat — Interpreting stat() results . . . 474
11.4 filecmp — File and Directory Comparisons . . . 480
11.4.1 The dircmp class . . . 481
11.5 tempfile — Generate temporary files and directories . . . 482
11.5.1 Examples . . . 486
11.5.2 Deprecated functions and variables . . . 487
11.6 glob — Unix style pathname pattern expansion . . . 488
11.6.1 Examples . . . 490
11.7 fnmatch — Unix filename pattern matching . . . 490

11.8 linecache — Random access to text lines . . . 492
11.9 shutil — High-level file operations . . . 492
11.9.1 Directory and files operations . . . 493
11.9.2 Archiving operations . . . 499
11.9.3 Querying the size of the output terminal . . . 502

12 Data Persistence **503**
12.1 pickle — Python object serialization . . . 503
12.1.1 Relationship to other Python modules . . . 503
12.1.2 Data stream format . . . 504
12.1.3 Module Interface . . . 505
12.1.4 What can be pickled and unpickled? . . . 508
12.1.5 Pickling Class Instances . . . 509
12.1.6 Custom Reduction for Types, Functions, and Other Objects . . . 515
12.1.7 Out-of-band Buffers . . . 515
12.1.8 Restricting Globals . . . 517
12.1.9 Performance . . . 518
12.1.10 Examples . . . 518
12.2 copyreg — Register pickle support functions . . . 519
12.2.1 Example . . . 519
12.3 shelve — Python object persistence . . . 520
12.3.1 Restrictions . . . 521
12.3.2 Example . . . 522
12.4 marshal — Internal Python object serialization . . . 522
12.5 dbm — Interfaces to Unix “databases” . . . 524
12.5.1 dbm.sqlite3 — SQLite backend for dbm . . . 526
12.5.2 dbm.gnu — GNU database manager . . . 526
12.5.3 dbm.ndbm — New Database Manager . . . 528
12.5.4 dbm.dumb — Portable DBM implementation . . . 529
12.6 sqlite3 — DB-API 2.0 interface for SQLite databases . . . 530
12.6.1 Tutorial . . . 530
12.6.2 Reference . . . 532
12.6.3 How-to guides . . . 553
12.6.4 Explanation . . . 560

13 Data Compression and Archiving **563**
13.1 zlib — Compression compatible with **gzip** . . . 563
13.2 gzip — Support for **gzip** files . . . 567
13.2.1 Examples of usage . . . 569
13.2.2 Command Line Interface . . . 570
13.3 bz2 — Support for **bzip2** compression . . . 570
13.3.1 (De)compression of files . . . 570
13.3.2 Incremental (de)compression . . . 572
13.3.3 One-shot (de)compression . . . 573
13.3.4 Examples of usage . . . 573
13.4 lzma — Compression using the LZMA algorithm . . . 575
13.4.1 Reading and writing compressed files . . . 575
13.4.2 Compressing and decompressing data in memory . . . 576
13.4.3 Miscellaneous . . . 578
13.4.4 Specifying custom filter chains . . . 578
13.4.5 Examples . . . 579
13.5 zipfile — Work with ZIP archives . . . 580
13.5.1 ZipFile Objects . . . 582
13.5.2 Path Objects . . . 586
13.5.3 PyZipFile Objects . . . 587
13.5.4 ZipInfo Objects . . . 588
13.5.5 Command-Line Interface . . . 590
13.5.6 Decompression pitfalls . . . 591

13.6 tarfile — Read and write tar archive files . . . 591
13.6.1 TarFile Objects . . . 595
13.6.2 TarInfo Objects . . . 598
13.6.3 Extraction filters . . . 601
13.6.4 Command-Line Interface . . . 604
13.6.5 Examples . . . 605
13.6.6 Supported tar formats . . . 606
13.6.7 Unicode issues . . . 606

14 File Formats **609**
14.1 csv — CSV File Reading and Writing . . . 609
14.1.1 Module Contents . . . 609
14.1.2 Dialects and Formatting Parameters . . . 613
14.1.3 Reader Objects . . . 614
14.1.4 Writer Objects . . . 615
14.1.5 Examples . . . 615
14.2 configparser — Configuration file parser . . . 616
14.2.1 Quick Start . . . 617
14.2.2 Supported Datatypes . . . 618
14.2.3 Fallback Values . . . 619
14.2.4 Supported INI File Structure . . . 620
14.2.5 Unnamed Sections . . . 621
14.2.6 Interpolation of values . . . 621
14.2.7 Mapping Protocol Access . . . 622
14.2.8 Customizing Parser Behaviour . . . 623
14.2.9 Legacy API Examples . . . 627
14.2.10 ConfigParser Objects . . . 629
14.2.11 RawConfigParser Objects . . . 633
14.2.12 Exceptions . . . 634
14.3 tomllib — Parse TOML files . . . 634
14.3.1 Examples . . . 635
14.3.2 Conversion Table . . . 636
14.4 netrc — netrc file processing . . . 636
14.4.1 netrc Objects . . . 637
14.5 plistlib — Generate and parse Apple .plist files . . . 637
14.5.1 Examples . . . 639

15 Cryptographic Services **641**
15.1 hashlib — Secure hashes and message digests . . . 641
15.1.1 Hash algorithms . . . 641
15.1.2 Usage . . . 642
15.1.3 Constructors . . . 642
15.1.4 Attributes . . . 643
15.1.5 Hash Objects . . . 643
15.1.6 SHAKE variable length digests . . . 643
15.1.7 File hashing . . . 644
15.1.8 Key derivation . . . 644
15.1.9 BLAKE2 . . . 645
15.2 hmac — Keyed-Hashing for Message Authentication . . . 652
15.3 secrets — Generate secure random numbers for managing secrets . . . 654
15.3.1 Random numbers . . . 654
15.3.2 Generating tokens . . . 654
15.3.3 Other functions . . . 655
15.3.4 Recipes and best practices . . . 655

16 Generic Operating System Services **657**
16.1 os — Miscellaneous operating system interfaces . . . 657
16.1.1 File Names, Command Line Arguments, and Environment Variables . . . 658
16.1.2 Python UTF-8 Mode . . . 658

16.1.3 Process Parameters . . . 659
16.1.4 File Object Creation . . . 666
16.1.5 File Descriptor Operations . . . 666
16.1.6 Files and Directories . . . 679
16.1.7 Process Management . . . 705
16.1.8 Interface to the scheduler . . . 718
16.1.9 Miscellaneous System Information . . . 720
16.1.10 Random numbers . . . 721
16.2 io — Core tools for working with streams . . . 723
16.2.1 Overview . . . 723
16.2.2 Text Encoding . . . 724
16.2.3 High-level Module Interface . . . 724
16.2.4 Class hierarchy . . . 725
16.2.5 Performance . . . 736
16.3 time — Time access and conversions . . . 736
16.3.1 Functions . . . 737
16.3.2 Clock ID Constants . . . 746
16.3.3 Timezone Constants . . . 748
16.4 logging — Logging facility for Python . . . 748
16.4.1 Logger Objects . . . 750
16.4.2 Logging Levels . . . 754
16.4.3 Handler Objects . . . 755
16.4.4 Formatter Objects . . . 757
16.4.5 Filter Objects . . . 758
16.4.6 LogRecord Objects . . . 759
16.4.7 LogRecord attributes . . . 760
16.4.8 LoggerAdapter Objects . . . 762
16.4.9 Thread Safety . . . 762
16.4.10 Module-Level Functions . . . 762
16.4.11 Module-Level Attributes . . . 766
16.4.12 Integration with the warnings module . . . 767
16.5 logging.config — Logging configuration . . . 767
16.5.1 Configuration functions . . . 768
16.5.2 Security considerations . . . 770
16.5.3 Configuration dictionary schema . . . 770
16.5.4 Configuration file format . . . 777
16.6 logging.handlers — Logging handlers . . . 779
16.6.1 StreamHandler . . . 780
16.6.2 FileHandler . . . 780
16.6.3 NullHandler . . . 781
16.6.4 WatchedFileHandler . . . 781
16.6.5 BaseRotatingHandler . . . 782
16.6.6 RotatingFileHandler . . . 783
16.6.7 TimedRotatingFileHandler . . . 783
16.6.8 SocketHandler . . . 785
16.6.9 DatagramHandler . . . 786
16.6.10 SysLogHandler . . . 786
16.6.11 NTEventLogHandler . . . 788
16.6.12 SMTPHandler . . . 789
16.6.13 MemoryHandler . . . 789
16.6.14 HTTPHandler . . . 790
16.6.15 QueueHandler . . . 791
16.6.16 QueueListener . . . 792
16.7 platform — Access to underlying platform's identifying data . . . 793
16.7.1 Cross platform . . . 793
16.7.2 Java platform . . . 795
16.7.3 Windows platform . . . 795
16.7.4 macOS platform . . . 796

16.7.5 iOS platform . . . 796
16.7.6 Unix platforms . . . 796
16.7.7 Linux platforms . . . 796
16.7.8 Android platform . . . 797
16.7.9 Command-line usage . . . 797
16.8 errno — Standard errno system symbols . . . 797
16.9 ctypes — A foreign function library for Python . . . 806
16.9.1 ctypes tutorial . . . 806
16.9.2 ctypes reference . . . 824

17 Command Line Interface Libraries **841**
17.1 argparse — Parser for command-line options, arguments and subcommands . . . 841
17.1.1 ArgumentParser objects . . . 842
17.1.2 The add_argument() method . . . 849
17.1.3 The parse_args() method . . . 859
17.1.4 Other utilities . . . 862
17.1.5 Exceptions . . . 871
17.2 optparse — Parser for command line options . . . 885
17.2.1 Choosing an argument parsing library . . . 885
17.2.2 Introduction . . . 886
17.2.3 Background . . . 887
17.2.4 Tutorial . . . 889
17.2.5 Reference Guide . . . 896
17.2.6 Option Callbacks . . . 905
17.2.7 Extending optparse . . . 909
17.2.8 Exceptions . . . 912
17.3 getpass — Portable password input . . . 912
17.4 fileinput — Iterate over lines from multiple input streams . . . 913
17.5 curses — Terminal handling for character-cell displays . . . 915
17.5.1 Functions . . . 916
17.5.2 Window Objects . . . 922
17.5.3 Constants . . . 929
17.6 curses.textpad — Text input widget for curses programs . . . 940
17.6.1 Textbox objects . . . 940
17.7 curses.ascii — Utilities for ASCII characters . . . 941
17.8 curses.panel — A panel stack extension for curses . . . 945
17.8.1 Functions . . . 945
17.8.2 Panel Objects . . . 945

18 Concurrent Execution **947**
18.1 threading — Thread-based parallelism . . . 947
18.1.1 Introduction . . . 947
18.1.2 GIL and performance considerations . . . 948
18.1.3 Reference . . . 948
18.1.4 Using locks, conditions, and semaphores in the with statement . . . 963
18.2 multiprocessing — Process-based parallelism . . . 963
18.2.1 Introduction . . . 963
18.2.2 Reference . . . 970
18.2.3 Programming guidelines . . . 999
18.2.4 Examples . . . 1002
18.3 multiprocessing.shared_memory — Shared memory for direct access across processes . . . 1007
18.4 The concurrent package . . . 1013
18.5 concurrent.futures — Launching parallel tasks . . . 1013
18.5.1 Executor Objects . . . 1014
18.5.2 ThreadPoolExecutor . . . 1015
18.5.3 ProcessPoolExecutor . . . 1016
18.5.4 Future Objects . . . 1018
18.5.5 Module Functions . . . 1019

18.5.6 Exception classes . . . 1020
18.6 subprocess — Subprocess management . . . 1021
18.6.1 Using the subprocess Module . . . 1021
18.6.2 Security Considerations . . . 1030
18.6.3 Popen Objects . . . 1030
18.6.4 Windows Popen Helpers . . . 1032
18.6.5 Older high-level API . . . 1034
18.6.6 Replacing Older Functions with the subprocess Module . . . 1036
18.6.7 Legacy Shell Invocation Functions . . . 1039
18.6.8 Notes . . . 1040
18.7 sched — Event scheduler . . . 1041
18.7.1 Scheduler Objects . . . 1042
18.8 queue — A synchronized queue class . . . 1042
18.8.1 Queue Objects . . . 1043
18.8.2 SimpleQueue Objects . . . 1045
18.9 contextvars — Context Variables . . . 1046
18.9.1 Context Variables . . . 1046
18.9.2 Manual Context Management . . . 1047
18.9.3 asyncio support . . . 1049
18.10 _thread — Low-level threading API . . . 1050

19 Networking and Interprocess Communication 1053
19.1 asyncio — Asynchronous I/O . . . 1053
19.1.1 Runners . . . 1054
19.1.2 Coroutines and Tasks . . . 1056
19.1.3 Streams . . . 1075
19.1.4 Synchronization Primitives . . . 1083
19.1.5 Subprocesses . . . 1089
19.1.6 Queues . . . 1093
19.1.7 Exceptions . . . 1096
19.1.8 Event Loop . . . 1097
19.1.9 Futures . . . 1121
19.1.10 Transports and Protocols . . . 1124
19.1.11 Policies . . . 1137
19.1.12 Platform Support . . . 1141
19.1.13 Extending . . . 1142
19.1.14 High-level API Index . . . 1143
19.1.15 Low-level API Index . . . 1146
19.1.16 Developing with asyncio . . . 1150
19.2 socket — Low-level networking interface . . . 1153
19.2.1 Socket families . . . 1154
19.2.2 Module contents . . . 1157
19.2.3 Socket Objects . . . 1170
19.2.4 Notes on socket timeouts . . . 1177
19.2.5 Example . . . 1177
19.3 ssl — TLS/SSL wrapper for socket objects . . . 1181
19.3.1 Functions, Constants, and Exceptions . . . 1182
19.3.2 SSL Sockets . . . 1193
19.3.3 SSL Contexts . . . 1197
19.3.4 Certificates . . . 1206
19.3.5 Examples . . . 1208
19.3.6 Notes on non-blocking sockets . . . 1211
19.3.7 Memory BIO Support . . . 1212
19.3.8 SSL session . . . 1214
19.3.9 Security considerations . . . 1214
19.3.10 TLS 1.3 . . . 1215
19.4 select — Waiting for I/O completion . . . 1216
19.4.1 /dev/poll Polling Objects . . . 1218

19.4.2 Edge and Level Trigger Polling (epoll) Objects . . . 1219
19.4.3 Polling Objects . . . 1220
19.4.4 Kqueue Objects . . . 1221
19.4.5 Kevent Objects . . . 1221
19.5 selectors — High-level I/O multiplexing . . . 1223
19.5.1 Introduction . . . 1223
19.5.2 Classes . . . 1224
19.5.3 Examples . . . 1226
19.6 signal — Set handlers for asynchronous events . . . 1227
19.6.1 General rules . . . 1227
19.6.2 Module contents . . . 1227
19.6.3 Examples . . . 1234
19.6.4 Note on SIGPIPE . . . 1235
19.6.5 Note on Signal Handlers and Exceptions . . . 1235
19.7 mmap — Memory-mapped file support . . . 1236
19.7.1 MADV_* Constants . . . 1240
19.7.2 MAP_* Constants . . . 1241

20 Internet Data Handling **1243**
20.1 email — An email and MIME handling package . . . 1243
20.1.1 email.message: Representing an email message . . . 1244
20.1.2 email.parser: Parsing email messages . . . 1252
20.1.3 email.generator: Generating MIME documents . . . 1255
20.1.4 email.policy: Policy Objects . . . 1258
20.1.5 email.errors: Exception and Defect classes . . . 1264
20.1.6 email.headerregistry: Custom Header Objects . . . 1266
20.1.7 email.contentmanager: Managing MIME Content . . . 1271
20.1.8 email: Examples . . . 1274
20.1.9 email.message.Message: Representing an email message using the compat32 API . . . 1280
20.1.10 email.mime: Creating email and MIME objects from scratch . . . 1288
20.1.11 email.header: Internationalized headers . . . 1291
20.1.12 email.charset: Representing character sets . . . 1293
20.1.13 email.encoders: Encoders . . . 1295
20.1.14 email.utils: Miscellaneous utilities . . . 1296
20.1.15 email.iterators: Iterators . . . 1298
20.2 json — JSON encoder and decoder . . . 1299
20.2.1 Basic Usage . . . 1302
20.2.2 Encoders and Decoders . . . 1304
20.2.3 Exceptions . . . 1306
20.2.4 Standard Compliance and Interoperability . . . 1307
20.2.5 Command Line Interface . . . 1308
20.3 mailbox — Manipulate mailboxes in various formats . . . 1309
20.3.1 Mailbox objects . . . 1310
20.3.2 Message objects . . . 1319
20.3.3 Exceptions . . . 1327
20.3.4 Examples . . . 1327
20.4 mimetypes — Map filenames to MIME types . . . 1328
20.4.1 MimeTypes Objects . . . 1330
20.5 base64 — Base16, Base32, Base64, Base85 Data Encodings . . . 1331
20.5.1 RFC 4648 Encodings . . . 1332
20.5.2 Base85 Encodings . . . 1333
20.5.3 Legacy Interface . . . 1334
20.5.4 Security Considerations . . . 1335
20.6 binascii — Convert between binary and ASCII . . . 1335
20.7 quopri — Encode and decode MIME quoted-printable data . . . 1337

21 Structured Markup Processing Tools **1339**
21.1 html — HyperText Markup Language support . . . 1339

21.2 html.parser — Simple HTML and XHTML parser . . . 1339
21.2.1 Example HTML Parser Application . . . 1340
21.2.2 HTMLParser Methods . . . 1340
21.2.3 Examples . . . 1342
21.3 html.entities — Definitions of HTML general entities . . . 1344
21.4 XML Processing Modules . . . 1344
21.4.1 XML vulnerabilities . . . 1345
21.4.2 The defusedxml Package . . . 1346
21.5 xml.etree.ElementTree — The ElementTree XML API . . . 1346
21.5.1 Tutorial . . . 1346
21.5.2 XPath support . . . 1351
21.5.3 Reference . . . 1353
21.5.4 XInclude support . . . 1356
21.5.5 Reference . . . 1357
21.6 xml.dom — The Document Object Model API . . . 1365
21.6.1 Module Contents . . . 1366
21.6.2 Objects in the DOM . . . 1367
21.6.3 Conformance . . . 1374
21.7 xml.dom.minidom — Minimal DOM implementation . . . 1375
21.7.1 DOM Objects . . . 1377
21.7.2 DOM Example . . . 1378
21.7.3 minidom and the DOM standard . . . 1379
21.8 xml.dom.pulldom — Support for building partial DOM trees . . . 1379
21.8.1 DOMEventStream Objects . . . 1381
21.9 xml.sax — Support for SAX2 parsers . . . 1381
21.9.1 SAXException Objects . . . 1383
21.10 xml.sax.handler — Base classes for SAX handlers . . . 1383
21.10.1 ContentHandler Objects . . . 1385
21.10.2 DTDHandler Objects . . . 1387
21.10.3 EntityResolver Objects . . . 1387
21.10.4 ErrorHandler Objects . . . 1387
21.10.5 LexicalHandler Objects . . . 1388
21.11 xml.sax.saxutils — SAX Utilities . . . 1388
21.12 xml.sax.xmlreader — Interface for XML parsers . . . 1389
21.12.1 XMLReader Objects . . . 1390
21.12.2 IncrementalParser Objects . . . 1391
21.12.3 Locator Objects . . . 1392
21.12.4 InputSource Objects . . . 1392
21.12.5 The Attributes Interface . . . 1393
21.12.6 The AttributesNS Interface . . . 1393
21.13 xml.parsers.expat — Fast XML parsing using Expat . . . 1393
21.13.1 XMLParser Objects . . . 1394
21.13.2 ExpatError Exceptions . . . 1398
21.13.3 Example . . . 1399
21.13.4 Content Model Descriptions . . . 1400
21.13.5 Expat error constants . . . 1400

22 Internet Protocols and Support **1403**
22.1 webbrowser — Convenient web-browser controller . . . 1403
22.1.1 Browser Controller Objects . . . 1405
22.2 wsgiref — WSGI Utilities and Reference Implementation . . . 1406
22.2.1 wsgiref.util – WSGI environment utilities . . . 1406
22.2.2 wsgiref.headers – WSGI response header tools . . . 1408
22.2.3 wsgiref.simple_server – a simple WSGI HTTP server . . . 1409
22.2.4 wsgiref.validate — WSGI conformance checker . . . 1410
22.2.5 wsgiref.handlers – server/gateway base classes . . . 1411
22.2.6 wsgiref.types – WSGI types for static type checking . . . 1414
22.2.7 Examples . . . 1415

22.3 urllib — URL handling modules . . . 1416
22.4 urllib.request — Extensible library for opening URLs . . . 1416
22.4.1 Request Objects . . . 1421
22.4.2 OpenerDirector Objects . . . 1423
22.4.3 BaseHandler Objects . . . 1424
22.4.4 HTTPRedirectHandler Objects . . . 1425
22.4.5 HTTPCookieProcessor Objects . . . 1426
22.4.6 ProxyHandler Objects . . . 1426
22.4.7 HTTPPasswordMgr Objects . . . 1426
22.4.8 HTTPPasswordMgrWithPriorAuth Objects . . . 1426
22.4.9 AbstractBasicAuthHandler Objects . . . 1427
22.4.10 HTTPBasicAuthHandler Objects . . . 1427
22.4.11 ProxyBasicAuthHandler Objects . . . 1427
22.4.12 AbstractDigestAuthHandler Objects . . . 1427
22.4.13 HTTPDigestAuthHandler Objects . . . 1427
22.4.14 ProxyDigestAuthHandler Objects . . . 1427
22.4.15 HTTPHandler Objects . . . 1427
22.4.16 HTTPSHandler Objects . . . 1427
22.4.17 FileHandler Objects . . . 1427
22.4.18 DataHandler Objects . . . 1428
22.4.19 FTPHandler Objects . . . 1428
22.4.20 CacheFTPHandler Objects . . . 1428
22.4.21 UnknownHandler Objects . . . 1428
22.4.22 HTTPErrorProcessor Objects . . . 1428
22.4.23 Examples . . . 1428
22.4.24 Legacy interface . . . 1431
22.4.25 urllib.request Restrictions . . . 1433
22.5 urllib.response — Response classes used by urllib . . . 1434
22.6 urllib.parse — Parse URLs into components . . . 1434
22.6.1 URL Parsing . . . 1435
22.6.2 URL parsing security . . . 1439
22.6.3 Parsing ASCII Encoded Bytes . . . 1440
22.6.4 Structured Parse Results . . . 1440
22.6.5 URL Quoting . . . 1441
22.7 urllib.error — Exception classes raised by urllib.request . . . 1443
22.8 urllib.robotparser — Parser for robots.txt . . . 1444
22.9 http — HTTP modules . . . 1445
22.9.1 HTTP status codes . . . 1446
22.9.2 HTTP status category . . . 1447
22.9.3 HTTP methods . . . 1448
22.10 http.client — HTTP protocol client . . . 1448
22.10.1 HTTPConnection Objects . . . 1451
22.10.2 HTTPResponse Objects . . . 1453
22.10.3 Examples . . . 1454
22.10.4 HTTPMessage Objects . . . 1456
22.11 ftplib — FTP protocol client . . . 1456
22.11.1 Reference . . . 1457
22.12 poplib — POP3 protocol client . . . 1463
22.12.1 POP3 Objects . . . 1464
22.12.2 POP3 Example . . . 1465
22.13 imaplib — IMAP4 protocol client . . . 1466
22.13.1 IMAP4 Objects . . . 1467
22.13.2 IMAP4 Example . . . 1472
22.14 smtplib — SMTP protocol client . . . 1472
22.14.1 SMTP Objects . . . 1474
22.14.2 SMTP Example . . . 1478
22.15 uuid — UUID objects according to **RFC 4122** . . . 1479
22.15.1 Command-Line Usage . . . 1482

22.15.2 Example . . . 1482
22.15.3 Command-Line Example . . . 1483
22.16 socketserver — A framework for network servers . . . 1483
22.16.1 Server Creation Notes . . . 1484
22.16.2 Server Objects . . . 1485
22.16.3 Request Handler Objects . . . 1487
22.16.4 Examples . . . 1488
22.17 http.server — HTTP servers . . . 1492
22.17.1 Command-line interface . . . 1497
22.17.2 Security considerations . . . 1498
22.18 http.cookies — HTTP state management . . . 1498
22.18.1 Cookie Objects . . . 1499
22.18.2 Morsel Objects . . . 1499
22.18.3 Example . . . 1501
22.19 http.cookiejar — Cookie handling for HTTP clients . . . 1502
22.19.1 CookieJar and FileCookieJar Objects . . . 1503
22.19.2 FileCookieJar subclasses and co-operation with web browsers . . . 1505
22.19.3 CookiePolicy Objects . . . 1506
22.19.4 DefaultCookiePolicy Objects . . . 1506
22.19.5 Cookie Objects . . . 1508
22.19.6 Examples . . . 1509
22.20 xmlrpc — XMLRPC server and client modules . . . 1510
22.21 xmlrpc.client — XML-RPC client access . . . 1510
22.21.1 ServerProxy Objects . . . 1512
22.21.2 DateTime Objects . . . 1513
22.21.3 Binary Objects . . . 1514
22.21.4 Fault Objects . . . 1514
22.21.5 ProtocolError Objects . . . 1515
22.21.6 MultiCall Objects . . . 1516
22.21.7 Convenience Functions . . . 1517
22.21.8 Example of Client Usage . . . 1517
22.21.9 Example of Client and Server Usage . . . 1518
22.22 xmlrpc.server — Basic XML-RPC servers . . . 1518
22.22.1 SimpleXMLRPCServer Objects . . . 1519
22.22.2 CGIXMLRPCRequestHandler . . . 1522
22.22.3 Documenting XMLRPC server . . . 1523
22.22.4 DocXMLRPCServer Objects . . . 1523
22.22.5 DocCGIXMLRPCRequestHandler . . . 1523
22.23 ipaddress — IPv4/IPv6 manipulation library . . . 1524
22.23.1 Convenience factory functions . . . 1524
22.23.2 IP Addresses . . . 1525
22.23.3 IP Network definitions . . . 1529
22.23.4 Interface objects . . . 1535
22.23.5 Other Module Level Functions . . . 1536
22.23.6 Custom Exceptions . . . 1537

23 Multimedia Services **1539**
23.1 wave — Read and write WAV files . . . 1539
23.1.1 Wave_read Objects . . . 1539
23.1.2 Wave_write Objects . . . 1540
23.2 colorsys — Conversions between color systems . . . 1542

24 Internationalization **1543**
24.1 gettext — Multilingual internationalization services . . . 1543
24.1.1 GNU **gettext** API . . . 1543
24.1.2 Class-based API . . . 1544
24.1.3 Internationalizing your programs and modules . . . 1548
24.1.4 Acknowledgements . . . 1550

24.2 locale — Internationalization services . . . 1551
24.2.1 Background, details, hints, tips and caveats . . . 1558
24.2.2 For extension writers and programs that embed Python . . . 1558
24.2.3 Access to message catalogs . . . 1558

25 Program Frameworks **1559**
25.1 turtle — Turtle graphics . . . 1559
25.1.1 Introduction . . . 1559
25.1.2 Get started . . . 1559
25.1.3 Tutorial . . . 1560
25.1.4 How to… . . . 1561
25.1.5 Turtle graphics reference . . . 1563
25.1.6 Methods of RawTurtle/Turtle and corresponding functions . . . 1565
25.1.7 Methods of TurtleScreen/Screen and corresponding functions . . . 1582
25.1.8 Public classes . . . 1589
25.1.9 Explanation . . . 1590
25.1.10 Help and configuration . . . 1591
25.1.11 turtledemo — Demo scripts . . . 1593
25.1.12 Changes since Python 2.6 . . . 1594
25.1.13 Changes since Python 3.0 . . . 1594
25.2 cmd — Support for line-oriented command interpreters . . . 1595
25.2.1 Cmd Objects . . . 1595
25.2.2 Cmd Example . . . 1597
25.3 shlex — Simple lexical analysis . . . 1600
25.3.1 shlex Objects . . . 1601
25.3.2 Parsing Rules . . . 1603
25.3.3 Improved Compatibility with Shells . . . 1604

26 Graphical User Interfaces with Tk **1607**
26.1 tkinter — Python interface to Tcl/Tk . . . 1607
26.1.1 Architecture . . . 1608
26.1.2 Tkinter Modules . . . 1608
26.1.3 Tkinter Life Preserver . . . 1610
26.1.4 Threading model . . . 1613
26.1.5 Handy Reference . . . 1614
26.1.6 File Handlers . . . 1619
26.2 tkinter.colorchooser — Color choosing dialog . . . 1620
26.3 tkinter.font — Tkinter font wrapper . . . 1620
26.4 Tkinter Dialogs . . . 1621
26.4.1 tkinter.simpledialog — Standard Tkinter input dialogs . . . 1621
26.4.2 tkinter.filedialog — File selection dialogs . . . 1622
26.4.3 tkinter.commondialog — Dialog window templates . . . 1624
26.5 tkinter.messagebox — Tkinter message prompts . . . 1624
26.6 tkinter.scrolledtext — Scrolled Text Widget . . . 1626
26.7 tkinter.dnd — Drag and drop support . . . 1627
26.8 tkinter.ttk — Tk themed widgets . . . 1628
26.8.1 Using Ttk . . . 1628
26.8.2 Ttk Widgets . . . 1628
26.8.3 Widget . . . 1629
26.8.4 Combobox . . . 1631
26.8.5 Spinbox . . . 1632
26.8.6 Notebook . . . 1633
26.8.7 Progressbar . . . 1635
26.8.8 Separator . . . 1635
26.8.9 Sizegrip . . . 1636
26.8.10 Treeview . . . 1636
26.8.11 Ttk Styling . . . 1641
26.9 IDLE — Python editor and shell . . . 1646

26.9.1 Menus . . . 1646
26.9.2 Editing and Navigation . . . 1650
26.9.3 Startup and Code Execution . . . 1653
26.9.4 Help and Preferences . . . 1656
26.9.5 idlelib — implementation of IDLE application . . . 1657

27 Development Tools **1659**
27.1 `typing` — Support for type hints . . . 1659
27.1.1 Specification for the Python Type System . . . 1660
27.1.2 Type aliases . . . 1660
27.1.3 NewType . . . 1660
27.1.4 Annotating callable objects . . . 1662
27.1.5 Generics . . . 1663
27.1.6 Annotating tuples . . . 1664
27.1.7 The type of class objects . . . 1665
27.1.8 Annotating generators and coroutines . . . 1665
27.1.9 User-defined generic types . . . 1666
27.1.10 The `Any` type . . . 1669
27.1.11 Nominal vs structural subtyping . . . 1670
27.1.12 Module contents . . . 1671
27.1.13 Deprecation Timeline of Major Features . . . 1712
27.2 `pydoc` — Documentation generator and online help system . . . 1712
27.3 Python Development Mode . . . 1713
27.3.1 Effects of the Python Development Mode . . . 1714
27.3.2 ResourceWarning Example . . . 1715
27.3.3 Bad file descriptor error example . . . 1716
27.4 `doctest` — Test interactive Python examples . . . 1716
27.4.1 Simple Usage: Checking Examples in Docstrings . . . 1718
27.4.2 Simple Usage: Checking Examples in a Text File . . . 1719
27.4.3 Command-line Usage . . . 1720
27.4.4 How It Works . . . 1720
27.4.5 Basic API . . . 1727
27.4.6 Unittest API . . . 1729
27.4.7 Advanced API . . . 1731
27.4.8 Debugging . . . 1736
27.4.9 Soapbox . . . 1738
27.5 `unittest` — Unit testing framework . . . 1739
27.5.1 Basic example . . . 1740
27.5.2 Command-Line Interface . . . 1741
27.5.3 Test Discovery . . . 1743
27.5.4 Organizing test code . . . 1744
27.5.5 Re-using old test code . . . 1746
27.5.6 Skipping tests and expected failures . . . 1746
27.5.7 Distinguishing test iterations using subtests . . . 1748
27.5.8 Classes and functions . . . 1749
27.5.9 Class and Module Fixtures . . . 1768
27.5.10 Signal Handling . . . 1769
27.6 `unittest.mock` — mock object library . . . 1770
27.6.1 Quick Guide . . . 1770
27.6.2 The Mock Class . . . 1772
27.6.3 The patchers . . . 1790
27.6.4 MagicMock and magic method support . . . 1799
27.6.5 Helpers . . . 1802
27.6.6 Order of precedence of `side_effect`, `return_value` and *wraps* . . . 1810
27.7 `unittest.mock` — getting started . . . 1812
27.7.1 Using Mock . . . 1812
27.7.2 Patch Decorators . . . 1817
27.7.3 Further Examples . . . 1819

27.8 test — Regression tests package for Python . . . 1831
27.8.1 Writing Unit Tests for the test package . . . 1832
27.8.2 Running tests using the command-line interface . . . 1833
27.9 test.support — Utilities for the Python test suite . . . 1834
27.10 test.support.socket_helper — Utilities for socket tests . . . 1843
27.11 test.support.script_helper — Utilities for the Python execution tests . . . 1844
27.12 test.support.bytecode_helper — Support tools for testing correct bytecode generation . . . 1845
27.13 test.support.threading_helper — Utilities for threading tests . . . 1845
27.14 test.support.os_helper — Utilities for os tests . . . 1846
27.15 test.support.import_helper — Utilities for import tests . . . 1848
27.16 test.support.warnings_helper — Utilities for warnings tests . . . 1849

28 Debugging and Profiling **1853**
28.1 Audit events table . . . 1853
28.2 bdb — Debugger framework . . . 1857
28.3 faulthandler — Dump the Python traceback . . . 1862
28.3.1 Dumping the traceback . . . 1862
28.3.2 Fault handler state . . . 1863
28.3.3 Dumping the tracebacks after a timeout . . . 1863
28.3.4 Dumping the traceback on a user signal . . . 1863
28.3.5 Issue with file descriptors . . . 1863
28.3.6 Example . . . 1864
28.4 pdb — The Python Debugger . . . 1864
28.4.1 Debugger Commands . . . 1867
28.5 The Python Profilers . . . 1873
28.5.1 Introduction to the profilers . . . 1873
28.5.2 Instant User's Manual . . . 1873
28.5.3 profile and cProfile Module Reference . . . 1876
28.5.4 The Stats Class . . . 1877
28.5.5 What Is Deterministic Profiling? . . . 1879
28.5.6 Limitations . . . 1880
28.5.7 Calibration . . . 1880
28.5.8 Using a custom timer . . . 1881
28.6 timeit — Measure execution time of small code snippets . . . 1881
28.6.1 Basic Examples . . . 1881
28.6.2 Python Interface . . . 1882
28.6.3 Command-Line Interface . . . 1884
28.6.4 Examples . . . 1884
28.7 trace — Trace or track Python statement execution . . . 1886
28.7.1 Command-Line Usage . . . 1886
28.7.2 Programmatic Interface . . . 1887
28.8 tracemalloc — Trace memory allocations . . . 1889
28.8.1 Examples . . . 1889
28.8.2 API . . . 1893

29 Software Packaging and Distribution **1899**
29.1 ensurepip — Bootstrapping the pip installer . . . 1899
29.1.1 Command line interface . . . 1899
29.1.2 Module API . . . 1900
29.2 venv — Creation of virtual environments . . . 1901
29.2.1 Creating virtual environments . . . 1901
29.2.2 How venvs work . . . 1903
29.2.3 API . . . 1904
29.2.4 An example of extending EnvBuilder . . . 1907
29.3 zipapp — Manage executable Python zip archives . . . 1910
29.3.1 Basic Example . . . 1911
29.3.2 Command-Line Interface . . . 1911
29.3.3 Python API . . . 1911

29.3.4 Examples . . . 1912
29.3.5 Specifying the Interpreter . . . 1913
29.3.6 Creating Standalone Applications with zipapp . . . 1913
29.3.7 The Python Zip Application Archive Format . . . 1914

30 Python Runtime Services 1915
30.1 sys — System-specific parameters and functions . . . 1915
30.2 sys.monitoring — Execution event monitoring . . . 1941
30.2.1 Tool identifiers . . . 1941
30.2.2 Events . . . 1942
30.2.3 Turning events on and off . . . 1944
30.2.4 Registering callback functions . . . 1944
30.3 sysconfig — Provide access to Python's configuration information . . . 1945
30.3.1 Configuration variables . . . 1945
30.3.2 Installation paths . . . 1946
30.3.3 User scheme . . . 1947
30.3.4 Home scheme . . . 1947
30.3.5 Prefix scheme . . . 1948
30.3.6 Installation path functions . . . 1949
30.3.7 Other functions . . . 1950
30.3.8 Command-line usage . . . 1951
30.4 builtins — Built-in objects . . . 1951
30.5 __main__ — Top-level code environment . . . 1952
30.5.1 __name__ == '__main__' . . . 1952
30.5.2 __main__.py in Python Packages . . . 1954
30.5.3 import __main__ . . . 1955
30.6 warnings — Warning control . . . 1957
30.6.1 Warning Categories . . . 1957
30.6.2 The Warnings Filter . . . 1958
30.6.3 Temporarily Suppressing Warnings . . . 1960
30.6.4 Testing Warnings . . . 1961
30.6.5 Updating Code For New Versions of Dependencies . . . 1961
30.6.6 Available Functions . . . 1961
30.6.7 Available Context Managers . . . 1963
30.7 dataclasses — Data Classes . . . 1964
30.7.1 Module contents . . . 1965
30.7.2 Post-init processing . . . 1971
30.7.3 Class variables . . . 1971
30.7.4 Init-only variables . . . 1971
30.7.5 Frozen instances . . . 1972
30.7.6 Inheritance . . . 1972
30.7.7 Re-ordering of keyword-only parameters in __init__() . . . 1972
30.7.8 Default factory functions . . . 1973
30.7.9 Mutable default values . . . 1973
30.7.10 Descriptor-typed fields . . . 1974
30.8 contextlib — Utilities for with-statement contexts . . . 1975
30.8.1 Utilities . . . 1975
30.8.2 Examples and Recipes . . . 1984
30.8.3 Single use, reusable and reentrant context managers . . . 1987
30.9 abc — Abstract Base Classes . . . 1989
30.10 atexit — Exit handlers . . . 1994
30.10.1 atexit Example . . . 1995
30.11 traceback — Print or retrieve a stack traceback . . . 1996
30.11.1 Module-Level Functions . . . 1996
30.11.2 TracebackException Objects . . . 1999
30.11.3 StackSummary Objects . . . 2000
30.11.4 FrameSummary Objects . . . 2001
30.11.5 Examples of Using the Module-Level Functions . . . 2002

30.11.6 Examples of Using TracebackException . . . 2004
30.12 __future__ — Future statement definitions . . . 2006
30.12.1 Module Contents . . . 2006
30.13 gc — Garbage Collector interface . . . 2007
30.14 inspect — Inspect live objects . . . 2011
30.14.1 Types and members . . . 2011
30.14.2 Retrieving source code . . . 2016
30.14.3 Introspecting callables with the Signature object . . . 2017
30.14.4 Classes and functions . . . 2021
30.14.5 The interpreter stack . . . 2024
30.14.6 Fetching attributes statically . . . 2026
30.14.7 Current State of Generators, Coroutines, and Asynchronous Generators . . . 2027
30.14.8 Code Objects Bit Flags . . . 2028
30.14.9 Buffer flags . . . 2029
30.14.10 Command Line Interface . . . 2030
30.15 site — Site-specific configuration hook . . . 2030
30.15.1 sitecustomize . . . 2031
30.15.2 usercustomize . . . 2031
30.15.3 Readline configuration . . . 2031
30.15.4 Module contents . . . 2031
30.15.5 Command Line Interface . . . 2032

31 Custom Python Interpreters 2035
31.1 code — Interpreter base classes . . . 2035
31.1.1 Interactive Interpreter Objects . . . 2036
31.1.2 Interactive Console Objects . . . 2036
31.2 codeop — Compile Python code . . . 2037

32 Importing Modules 2039
32.1 zipimport — Import modules from Zip archives . . . 2039
32.1.1 zipimporter Objects . . . 2040
32.1.2 Examples . . . 2041
32.2 pkgutil — Package extension utility . . . 2041
32.3 modulefinder — Find modules used by a script . . . 2044
32.3.1 Example usage of ModuleFinder . . . 2044
32.4 runpy — Locating and executing Python modules . . . 2045
32.5 importlib — The implementation of import . . . 2048
32.5.1 Introduction . . . 2048
32.5.2 Functions . . . 2049
32.5.3 importlib.abc – Abstract base classes related to import . . . 2050
32.5.4 importlib.machinery – Importers and path hooks . . . 2057
32.5.5 importlib.util – Utility code for importers . . . 2062
32.5.6 Examples . . . 2065
32.6 importlib.resources – Package resource reading, opening and access . . . 2067
32.6.1 Functional API . . . 2069
32.7 importlib.resources.abc – Abstract base classes for resources . . . 2071
32.8 importlib.metadata – Accessing package metadata . . . 2072
32.8.1 Overview . . . 2073
32.8.2 Functional API . . . 2074
32.8.3 Distributions . . . 2077
32.8.4 Distribution Discovery . . . 2078
32.8.5 Extending the search algorithm . . . 2078
32.9 The initialization of the sys.path module search path . . . 2080
32.9.1 Virtual environments . . . 2080
32.9.2 _pth files . . . 2081
32.9.3 Embedded Python . . . 2081

33 Python Language Services 2083
33.1 ast — Abstract Syntax Trees . . . 2083

33.1.1 Abstract Grammar . . . 2083
33.1.2 Node classes . . . 2086
33.1.3 ast Helpers . . . 2116
33.1.4 Compiler Flags . . . 2120
33.1.5 Command-Line Usage . . . 2120
33.2 symtable — Access to the compiler's symbol tables . . . 2121
33.2.1 Generating Symbol Tables . . . 2121
33.2.2 Examining Symbol Tables . . . 2121
33.2.3 Command-Line Usage . . . 2124
33.3 token — Constants used with Python parse trees . . . 2125
33.4 keyword — Testing for Python keywords . . . 2130
33.5 tokenize — Tokenizer for Python source . . . 2130
33.5.1 Tokenizing Input . . . 2130
33.5.2 Command-Line Usage . . . 2132
33.5.3 Examples . . . 2132
33.6 tabnanny — Detection of ambiguous indentation . . . 2134
33.7 pyclbr — Python module browser support . . . 2135
33.7.1 Function Objects . . . 2135
33.7.2 Class Objects . . . 2136
33.8 py_compile — Compile Python source files . . . 2136
33.8.1 Command-Line Interface . . . 2138
33.9 compileall — Byte-compile Python libraries . . . 2138
33.9.1 Command-line use . . . 2138
33.9.2 Public functions . . . 2140
33.10 dis — Disassembler for Python bytecode . . . 2142
33.10.1 Command-line interface . . . 2143
33.10.2 Bytecode analysis . . . 2143
33.10.3 Analysis functions . . . 2144
33.10.4 Python Bytecode Instructions . . . 2146
33.10.5 Opcode collections . . . 2163
33.11 pickletools — Tools for pickle developers . . . 2164
33.11.1 Command line usage . . . 2164
33.11.2 Programmatic Interface . . . 2165

34 MS Windows Specific Services 2167
34.1 msvcrt — Useful routines from the MS VC++ runtime . . . 2167
34.1.1 File Operations . . . 2167
34.1.2 Console I/O . . . 2168
34.1.3 Other Functions . . . 2168
34.2 winreg — Windows registry access . . . 2169
34.2.1 Functions . . . 2170
34.2.2 Constants . . . 2175
34.2.3 Registry Handle Objects . . . 2177
34.3 winsound — Sound-playing interface for Windows . . . 2178

35 Unix Specific Services 2181
35.1 posix — The most common POSIX system calls . . . 2181
35.1.1 Large File Support . . . 2181
35.1.2 Notable Module Contents . . . 2181
35.2 pwd — The password database . . . 2182
35.3 grp — The group database . . . 2183
35.4 termios — POSIX style tty control . . . 2183
35.4.1 Example . . . 2184
35.5 tty — Terminal control functions . . . 2185
35.6 pty — Pseudo-terminal utilities . . . 2186
35.6.1 Example . . . 2187
35.7 fcntl — The fcntl and ioctl system calls . . . 2187
35.8 resource — Resource usage information . . . 2190

35.8.1 Resource Limits . . . 2190
35.8.2 Resource Usage . . . 2193
35.9 syslog — Unix syslog library routines . . . 2194
35.9.1 Examples . . . 2196

36 Modules command-line interface (CLI) 2199

37 Superseded Modules 2201
37.1 getopt — C-style parser for command line options . . . 2201

38 Removed Modules 2205
38.1 aifc — Read and write AIFF and AIFC files . . . 2205
38.2 asynchat — Asynchronous socket command/response handler . . . 2205
38.3 asyncore — Asynchronous socket handler . . . 2205
38.4 audioop — Manipulate raw audio data . . . 2205
38.5 cgi — Common Gateway Interface support . . . 2206
38.6 cgitb — Traceback manager for CGI scripts . . . 2206
38.7 chunk — Read IFF chunked data . . . 2206
38.8 crypt — Function to check Unix passwords . . . 2206
38.9 distutils — Building and installing Python modules . . . 2206
38.10 imghdr — Determine the type of an image . . . 2206
38.11 imp — Access the import internals . . . 2207
38.12 mailcap — Mailcap file handling . . . 2207
38.13 msilib — Read and write Microsoft Installer files . . . 2207
38.14 nis — Interface to Sun's NIS (Yellow Pages) . . . 2207
38.15 nntplib — NNTP protocol client . . . 2207
38.16 ossaudiodev — Access to OSS-compatible audio devices . . . 2207
38.17 pipes — Interface to shell pipelines . . . 2208
38.18 smtpd — SMTP Server . . . 2208
38.19 sndhdr — Determine type of sound file . . . 2208
38.20 spwd — The shadow password database . . . 2208
38.21 sunau — Read and write Sun AU files . . . 2208
38.22 telnetlib — Telnet client . . . 2208
38.23 uu — Encode and decode uuencode files . . . 2209
38.24 xdrlib — Encode and decode XDR data . . . 2209

39 Security Considerations 2211

Bibliography **2255**

Python Module Index **2257**

Index **2261**

While reference-index describes the exact syntax and semantics of the Python language, this library reference manual describes the standard library that is distributed with Python. It also describes some of the optional components that are commonly included in Python distributions.

Python's standard library is very extensive, offering a wide range of facilities as indicated by the long table of contents listed below. The library contains built-in modules (written in C) that provide access to system functionality such as file I/O that would otherwise be inaccessible to Python programmers, as well as modules written in Python that provide standardized solutions for many problems that occur in everyday programming. Some of these modules are explicitly designed to encourage and enhance the portability of Python programs by abstracting away platform-specifics into platform-neutral APIs.

The Python installers for the Windows platform usually include the entire standard library and often also include many additional components. For Unix-like operating systems Python is normally provided as a collection of packages, so it may be necessary to use the packaging tools provided with the operating system to obtain some or all of the optional components.

In addition to the standard library, there is an active collection of hundreds of thousands of components (from individual programs and modules to packages and entire application development frameworks), available from the Python Package Index.

CHAPTER

ONE

INTRODUCTION

The "Python library" contains several different kinds of components.

It contains data types that would normally be considered part of the "core" of a language, such as numbers and lists. For these types, the Python language core defines the form of literals and places some constraints on their semantics, but does not fully define the semantics. (On the other hand, the language core does define syntactic properties like the spelling and priorities of operators.)

The library also contains built-in functions and exceptions — objects that can be used by all Python code without the need of an `import` statement. Some of these are defined by the core language, but many are not essential for the core semantics and are only described here.

The bulk of the library, however, consists of a collection of modules. There are many ways to dissect this collection. Some modules are written in C and built in to the Python interpreter; others are written in Python and imported in source form. Some modules provide interfaces that are highly specific to Python, like printing a stack trace; some provide interfaces that are specific to particular operating systems, such as access to specific hardware; others provide interfaces that are specific to a particular application domain, like the World Wide Web. Some modules are available in all versions and ports of Python; others are only available when the underlying system supports or requires them; yet others are available only when a particular configuration option was chosen at the time when Python was compiled and installed.

This manual is organized "from the inside out:" it first describes the built-in functions, data types and exceptions, and finally the modules, grouped in chapters of related modules.

This means that if you start reading this manual from the start, and skip to the next chapter when you get bored, you will get a reasonable overview of the available modules and application areas that are supported by the Python library. Of course, you don't *have* to read it like a novel — you can also browse the table of contents (in front of the manual), or look for a specific function, module or term in the index (in the back). And finally, if you enjoy learning about random subjects, you choose a random page number (see module `random`) and read a section or two. Regardless of the order in which you read the sections of this manual, it helps to start with chapter *Built-in Functions*, as the remainder of the manual assumes familiarity with this material.

Let the show begin!

1.1 Notes on availability

- An "Availability: Unix" note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim "Availability: Unix" are supported on macOS, iOS and Android, all of which build on a Unix core.
- If an availability note contains both a minimum Kernel version and a minimum libc version, then both conditions must hold. For example a feature with note *Availability: Linux >= 3.17 with glibc >= 2.27* requires both Linux 3.17 or newer and glibc 2.27 or newer.

1.1.1 WebAssembly platforms

The WebAssembly platforms `wasm32-emscripten` (Emscripten) and `wasm32-wasi` (WASI) provide a subset of POSIX APIs. WebAssembly runtimes and browsers are sandboxed and have limited access to the host and external resources. Any Python standard library module that uses processes, threading, networking, signals, or other forms of inter-process communication (IPC), is either not available or may not work as on other Unix-like systems. File I/O, file system, and Unix permission-related functions are restricted, too. Emscripten does not permit blocking I/O. Other blocking operations like *sleep()* block the browser event loop.

The properties and behavior of Python on WebAssembly platforms depend on the Emscripten-SDK or WASI-SDK version, WASM runtimes (browser, NodeJS, wasmtime), and Python build time flags. WebAssembly, Emscripten, and WASI are evolving standards; some features like networking may be supported in the future.

For Python in the browser, users should consider Pyodide or PyScript. PyScript is built on top of Pyodide, which itself is built on top of CPython and Emscripten. Pyodide provides access to browsers' JavaScript and DOM APIs as well as limited networking capabilities with JavaScript's `XMLHttpRequest` and `Fetch` APIs.

- Process-related APIs are not available or always fail with an error. That includes APIs that spawn new processes (*fork()*, *execve()*), wait for processes (*waitpid()*), send signals (*kill()*), or otherwise interact with processes. The *subprocess* is importable but does not work.
- The *socket* module is available, but is limited and behaves differently from other platforms. On Emscripten, sockets are always non-blocking and require additional JavaScript code and helpers on the server to proxy TCP through WebSockets; see Emscripten Networking for more information. WASI snapshot preview 1 only permits sockets from an existing file descriptor.
- Some functions are stubs that either don't do anything and always return hardcoded values.
- Functions related to file descriptors, file permissions, file ownership, and links are limited and don't support some operations. For example, WASI does not permit symlinks with absolute file names.

1.1.2 Mobile platforms

Android and iOS are, in most respects, POSIX operating systems. File I/O, socket handling, and threading all behave as they would on any POSIX operating system. However, there are several major differences:

- Mobile platforms can only use Python in "embedded" mode. There is no Python REPL, and no ability to use separate executables such as **python** or **pip**. To add Python code to your mobile app, you must use the Python embedding API. For more details, see using-android and using-ios.
- Subprocesses:
  - On Android, creating subprocesses is possible but officially unsupported. In particular, Android does not support any part of the System V IPC API, so *multiprocessing* is not available.
  - An iOS app cannot use any form of subprocessing, multiprocessing, or inter-process communication. If an iOS app attempts to create a subprocess, the process creating the subprocess will either lock up, or crash. An iOS app has no visibility of other applications that are running, nor any ability to communicate with other running applications, outside of the iOS-specific APIs that exist for this purpose.
- Mobile apps have limited access to modify system resources (such as the system clock). These resources will often be *readable*, but attempts to modify those resources will usually fail.
- Console input and output:
  - On Android, the native `stdout` and `stderr` are not connected to anything, so Python installs its own streams which redirect messages to the system log. These can be seen under the tags `python.stdout` and `python.stderr` respectively.
  - iOS apps have a limited concept of console output. `stdout` and `stderr` *exist*, and content written to `stdout` and `stderr` will be visible in logs when running in Xcode, but this content *won't* be recorded in the system log. If a user who has installed your app provides their app logs as a diagnostic aid, they will not include any detail written to `stdout` or `stderr`.
  - Mobile apps have no usable `stdin` at all. While apps can display an on-screen keyboard, this is a software feature, not something that is attached to `stdin`.

As a result, Python modules that involve console manipulation (such as *curses* and *readline*) are not available on mobile platforms.

CHAPTER

TWO

BUILT-IN FUNCTIONS

The Python interpreter has a number of functions and types built into it that are always available. They are listed here in alphabetical order.

Built-in Functions

A
abs()
aiter()
all()
anext()
any()
ascii()

B
bin()
bool()
breakpoint()
bytearray()
bytes()

C
callable()
chr()
classmethod()
compile()
complex()

D
delattr()
dict()
dir()
divmod()

E
enumerate()
eval()
exec()

F
filter()
float()
format()
frozenset()

G
getattr()
globals()

H
hasattr()
hash()
help()
hex()

I
id()
input()
int()
isinstance()
issubclass()
iter()

L
len()
list()
locals()

M
map()
max()
memoryview()
min()

N
next()

O
object()
oct()
open()
ord()

P
pow()
print()
property()

R
range()
repr()
reversed()
round()

S
set()
setattr()
slice()
sorted()
staticmethod()
str()
sum()
super()

T
tuple()
type()

V
vars()

Z
zip()

_
__import__()

abs(*x*)

Return the absolute value of a number. The argument may be an integer, a floating-point number, or an object implementing `__abs__()`. If the argument is a complex number, its magnitude is returned.

aiter(*async_iterable*)

Return an *asynchronous iterator* for an *asynchronous iterable*. Equivalent to calling `x.__aiter__()`.

Note: Unlike *iter()*, *aiter()* has no 2-argument variant.

Added in version 3.10.

all(*iterable*)

Return `True` if all elements of the *iterable* are true (or if the iterable is empty). Equivalent to:

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

awaitable anext(*async_iterator*)

awaitable anext(*async_iterator*, *default*)

When awaited, return the next item from the given *asynchronous iterator*, or *default* if given and the iterator is exhausted.

This is the async variant of the *next()* builtin, and behaves similarly.

This calls the `__anext__()` method of *async_iterator*, returning an *awaitable*. Awaiting this returns the next value of the iterator. If *default* is given, it is returned if the iterator is exhausted, otherwise *StopAsyncIteration* is raised.

Added in version 3.10.

any(*iterable*)

Return `True` if any element of the *iterable* is true. If the iterable is empty, return `False`. Equivalent to:

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

ascii(*object*)

As *repr()*, return a string containing a printable representation of an object, but escape the non-ASCII characters in the string returned by *repr()* using `\x`, `\u`, or `\U` escapes. This generates a string similar to that returned by *repr()* in Python 2.

bin(*x*)

Convert an integer number to a binary string prefixed with "0b". The result is a valid Python expression. If *x* is not a Python *int* object, it has to define an `__index__()` method that returns an integer. Some examples:

```
>>> bin(3)
'0b11'
>>> bin(-10)
'-0b1010'
```

If the prefix "0b" is desired or not, you can use either of the following ways.

```
>>> format(14, '#b'), format(14, 'b')
('0b1110', '1110')
>>> f'{14:#b}', f'{14:b}'
('0b1110', '1110')
```

See also *format()* for more information.

class bool(*object=False*, */ (Positional-only parameter separator (PEP 570))*)

Return a Boolean value, i.e. one of `True` or `False`. The argument is converted using the standard *truth testing procedure*. If the argument is false or omitted, this returns `False`; otherwise, it returns `True`. The *bool* class is a subclass of *int* (see *Numeric Types — int, float, complex*). It cannot be subclassed further. Its only instances are `False` and `True` (see *Boolean Type - bool*).

Changed in version 3.7: The parameter is now positional-only.

breakpoint(**args*, ***kws*)

This function drops you into the debugger at the call site. Specifically, it calls *sys.breakpointhook()*, passing `args` and `kws` straight through. By default, `sys.breakpointhook()` calls *pdb.set_trace()* expecting no arguments. In this case, it is purely a convenience function so you don't have to explicitly import *pdb* or type as much code to enter the debugger. However, *sys.breakpointhook()* can be set to some other function and *breakpoint()* will automatically call that, allowing you to drop into the debugger of choice. If *sys.breakpointhook()* is not accessible, this function will raise *RuntimeError*.

By default, the behavior of *breakpoint()* can be changed with the `PYTHONBREAKPOINT` environment variable. See *sys.breakpointhook()* for usage details.

Note that this is not guaranteed if *sys.breakpointhook()* has been replaced.

Raises an *auditing event* `builtins.breakpoint` with argument `breakpointhook`.

Added in version 3.7.

class bytearray(*source=b''*)

class bytearray(*source*, *encoding*)

class bytearray(*source*, *encoding*, *errors*)

Return a new array of bytes. The *bytearray* class is a mutable sequence of integers in the range 0 <= x < 256. It has most of the usual methods of mutable sequences, described in *Mutable Sequence Types*, as well as most methods that the *bytes* type has, see *Bytes and Bytearray Operations*.

The optional *source* parameter can be used to initialize the array in a few different ways:

- If it is a *string*, you must also give the *encoding* (and optionally, *errors*) parameters; *bytearray()* then converts the string to bytes using *str.encode()*.
- If it is an *integer*, the array will have that size and will be initialized with null bytes.
- If it is an object conforming to the buffer interface, a read-only buffer of the object will be used to initialize the bytes array.
- If it is an *iterable*, it must be an iterable of integers in the range `0 <= x < 256`, which are used as the initial contents of the array.

Without an argument, an array of size 0 is created.

See also *Binary Sequence Types — bytes, bytearray, memoryview* and *Bytearray Objects*.

class bytes(*source=b''*)

class bytes(*source*, *encoding*)

class bytes(*source*, *encoding*, *errors*)

Return a new "bytes" object which is an immutable sequence of integers in the range `0 <= x < 256`. *bytes* is an immutable version of *bytearray* – it has the same non-mutating methods and the same indexing and slicing behavior.

Accordingly, constructor arguments are interpreted as for *bytearray()*.

Bytes objects can also be created with literals, see strings.

See also *Binary Sequence Types — bytes, bytearray, memoryview*, *Bytes Objects*, and *Bytes and Bytearray Operations*.

callable(*object*)

Return *True* if the *object* argument appears callable, *False* if not. If this returns `True`, it is still possible that a call fails, but if it is `False`, calling *object* will never succeed. Note that classes are callable (calling a class returns a new instance); instances are callable if their class has a `__call__()` method.

Added in version 3.2: This function was first removed in Python 3.0 and then brought back in Python 3.2.

chr(*i*)

Return the string representing a character whose Unicode code point is the integer *i*. For example, `chr(97)` returns the string `'a'`, while `chr(8364)` returns the string `'€'`. This is the inverse of *ord()*.

The valid range for the argument is from 0 through 1,114,111 (0x10FFFF in base 16). *ValueError* will be raised if *i* is outside that range.

@classmethod

Transform a method into a class method.

A class method receives the class as an implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom:

```
class C:
    @classmethod
    def f(cls, arg1, arg2): ...
```

The `@classmethod` form is a function *decorator* – see function for details.

A class method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Class methods are different than C++ or Java static methods. If you want those, see *staticmethod()* in this section. For more information on class methods, see types.

Changed in version 3.9: Class methods can now wrap other *descriptors* such as *property()*.

Changed in version 3.10: Class methods now inherit the method attributes (`__module__`, `__name__`, `__qualname__`, `__doc__` and `__annotations__`) and have a new `__wrapped__` attribute.

Deprecated since version 3.11, removed in version 3.13: Class methods can no longer wrap other *descriptors* such as *property()*.

compile(*source*, *filename*, *mode*, *flags=0*, *dont_inherit=False*, *optimize=-1*)

Compile the *source* into a code or AST object. Code objects can be executed by *exec()* or *eval()*. *source* can either be a normal string, a byte string, or an AST object. Refer to the *ast* module documentation for information on how to work with AST objects.

The *filename* argument should give the file from which the code was read; pass some recognizable value if it wasn't read from a file (`'<string>'` is commonly used).

The *mode* argument specifies what kind of code must be compiled; it can be `'exec'` if *source* consists of a sequence of statements, `'eval'` if it consists of a single expression, or `'single'` if it consists of a single interactive statement (in the latter case, expression statements that evaluate to something other than `None` will be printed).

The optional arguments *flags* and *dont_inherit* control which *compiler options* should be activated and which future features should be allowed. If neither is present (or both are zero) the code is compiled with the same flags that affect the code that is calling *compile()*. If the *flags* argument is given and *dont_inherit* is not (or is zero) then the compiler options and the future statements specified by the *flags* argument are used in addition to those that would be used anyway. If *dont_inherit* is a non-zero integer then the *flags* argument is it – the flags (future features and compiler options) in the surrounding code are ignored.

Compiler options and future statements are specified by bits which can be bitwise ORed together to specify multiple options. The bitfield required to specify a given future feature can be found as the *compiler_flag* attribute on the *_Feature* instance in the *__future__* module. *Compiler flags* can be found in *ast* module, with `PyCF_` prefix.

The argument *optimize* specifies the optimization level of the compiler; the default value of `-1` selects the optimization level of the interpreter as given by `-O` options. Explicit levels are `0` (no optimization; `__debug__` is true), `1` (asserts are removed, `__debug__` is false) or `2` (docstrings are removed too).

This function raises *`SyntaxError`* if the compiled source is invalid, and *`ValueError`* if the source contains null bytes.

If you want to parse Python code into its AST representation, see *`ast.parse()`*.

Raises an *auditing event* `compile` with arguments `source` and `filename`. This event may also be raised by implicit compilation.

Note

When compiling a string with multi-line code in `'single'` or `'eval'` mode, input must be terminated by at least one newline character. This is to facilitate detection of incomplete and complete statements in the *`code`* module.

Warning

It is possible to crash the Python interpreter with a sufficiently large/complex string when compiling to an AST object due to stack depth limitations in Python's AST compiler.

Changed in version 3.2: Allowed use of Windows and Mac newlines. Also, input in `'exec'` mode does not have to end in a newline anymore. Added the *optimize* parameter.

Changed in version 3.5: Previously, *`TypeError`* was raised when null bytes were encountered in *source*.

Added in version 3.8: `ast.PyCF_ALLOW_TOP_LEVEL_AWAIT` can now be passed in flags to enable support for top-level `await`, `async for`, and `async with`.

class complex(*number=0*, */*)

class complex(*string*, */*)

class complex(*real=0*, *imag=0*)

Convert a single string or number to a complex number, or create a complex number from real and imaginary parts.

Examples:

```
>>> complex('+1.23')
(1.23+0j)
>>> complex('-4.5j')
-4.5j
>>> complex('-1.23+4.5j')
(-1.23+4.5j)
>>> complex('\t( -1.23+4.5J )\n')
(-1.23+4.5j)
>>> complex('-Infinity+NaNj')
(-inf+nanj)
>>> complex(1.23)
(1.23+0j)
>>> complex(imag=-4.5)
-4.5j
>>> complex(-1.23, 4.5)
(-1.23+4.5j)
```

If the argument is a string, it must contain either a real part (in the same format as for *float()*) or an imaginary part (in the same format but with a `'j'` or `'J'` suffix), or both real and imaginary parts (the sign of the imaginary part is mandatory in this case). The string can optionally be surrounded by whitespaces and the round parentheses `'('` and `')'`, which are ignored. The string must not contain whitespace between `'+'`, `'-'`, the `'j'` or `'J'` suffix, and the decimal number. For example, `complex('1+2j')` is fine, but `complex('1 + 2j')` raises *ValueError*. More precisely, the input must conform to the *complexvalue* production rule in the following grammar, after parentheses and leading and trailing whitespace characters are removed:

```
complexvalue ::= floatvalue |
                 floatvalue ("j" | "J") |
                 floatvalue sign absfloatvalue ("j" | "J")
```

If the argument is a number, the constructor serves as a numeric conversion like *int* and *float*. For a general Python object `x`, `complex(x)` delegates to `x.__complex__()`. If `__complex__()` is not defined then it falls back to `__float__()`. If `__float__()` is not defined then it falls back to `__index__()`.

If two arguments are provided or keyword arguments are used, each argument may be any numeric type (including complex). If both arguments are real numbers, return a complex number with the real component *real* and the imaginary component *imag*. If both arguments are complex numbers, return a complex number with the real component `real.real-imag.imag` and the imaginary component `real.imag+imag.real`. If one of arguments is a real number, only its real component is used in the above expressions.

If all arguments are omitted, returns `0j`.

The complex type is described in *Numeric Types — int, float, complex*.

Changed in version 3.6: Grouping digits with underscores as in code literals is allowed.

Changed in version 3.8: Falls back to `__index__()` if `__complex__()` and `__float__()` are not defined.

delattr(*object*, *name*)

This is a relative of *setattr()*. The arguments are an object and a string. The string must be the name of one of the object's attributes. The function deletes the named attribute, provided the object allows it. For example, `delattr(x, 'foobar')` is equivalent to `del x.foobar`. *name* need not be a Python identifier (see *setattr()*).

class dict(***kwarg*)

class dict(*mapping*, ***kwarg*)

class dict(*iterable*, ***kwarg*)

Create a new dictionary. The *dict* object is the dictionary class. See *dict* and *Mapping Types — dict* for documentation about this class.

For other containers see the built-in *list*, *set*, and *tuple* classes, as well as the *collections* module.

dir()

dir(*object*)

Without arguments, return the list of names in the current local scope. With an argument, attempt to return a list of valid attributes for that object.

If the object has a method named `__dir__()`, this method will be called and must return the list of attributes. This allows objects that implement a custom `__getattr__()` or `__getattribute__()` function to customize the way *dir()* reports their attributes.

If the object does not provide `__dir__()`, the function tries its best to gather information from the object's `__dict__` attribute, if defined, and from its type object. The resulting list is not necessarily complete and may be inaccurate when the object has a custom `__getattr__()`.

The default *dir()* mechanism behaves differently with different types of objects, as it attempts to produce the most relevant, rather than complete, information:

- If the object is a module object, the list contains the names of the module's attributes.
- If the object is a type or class object, the list contains the names of its attributes, and recursively of the attributes of its bases.

- Otherwise, the list contains the object's attributes' names, the names of its class's attributes, and recursively of the attributes of its class's base classes.

The resulting list is sorted alphabetically. For example:

```
>>> import struct
>>> dir()   # show the names in the module namespace
['__builtins__', '__name__', 'struct']
>>> dir(struct)   # show the names in the struct module
['Struct', '__all__', '__builtins__', '__cached__', '__doc__', '__file__',
 '__initializing__', '__loader__', '__name__', '__package__',
 '_clearcache', 'calcsize', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape:
...     def __dir__(self):
...         return ['area', 'perimeter', 'location']
...
>>> s = Shape()
>>> dir(s)
['area', 'location', 'perimeter']
```

Note

Because *dir()* is supplied primarily as a convenience for use at an interactive prompt, it tries to supply an interesting set of names more than it tries to supply a rigorously or consistently defined set of names, and its detailed behavior may change across releases. For example, metaclass attributes are not in the result list when the argument is a class.

divmod(*a*, *b*)

Take two (non-complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using integer division. With mixed operand types, the rules for binary arithmetic operators apply. For integers, the result is the same as `(a // b, a % b)`. For floating-point numbers the result is `(q, a % b)`, where *q* is usually `math.floor(a / b)` but may be 1 less than that. In any case `q * b + a % b` is very close to *a*, if `a % b` is non-zero it has the same sign as *b*, and `0 <= abs(a % b) < abs(b)`.

enumerate(*iterable*, *start=0*)

Return an enumerate object. *iterable* must be a sequence, an *iterator*, or some other object which supports iteration. The *__next__()* method of the iterator returned by *enumerate()* returns a tuple containing a count (from *start* which defaults to 0) and the values obtained from iterating over *iterable*.

```
>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]
```

Equivalent to:

```
def enumerate(iterable, start=0):
    n = start
    for elem in iterable:
        yield n, elem
        n += 1
```

eval(*source*, */*, *globals=None*, *locals=None*)

Parameters

- **source** (*str* | code object) – A Python expression.

- **globals** (*dict* | None) – The global namespace (default: None).
- **locals** (*mapping* | None) – The local namespace (default: None).

Returns
The result of the evaluated expression.

Raises
Syntax errors are reported as exceptions.

> **Warning**
>
> This function executes arbitrary code. Calling it with user-supplied input may lead to security vulnerabilities.

The *expression* argument is parsed and evaluated as a Python expression (technically speaking, a condition list) using the *globals* and *locals* mappings as global and local namespace. If the *globals* dictionary is present and does not contain a value for the key __builtins__, a reference to the dictionary of the built-in module *builtins* is inserted under that key before *expression* is parsed. That way you can control what builtins are available to the executed code by inserting your own __builtins__ dictionary into *globals* before passing it to *eval()*. If the *locals* mapping is omitted it defaults to the *globals* dictionary. If both mappings are omitted, the expression is executed with the *globals* and *locals* in the environment where *eval()* is called. Note, *eval()* will only have access to the *nested scopes* (non-locals) in the enclosing environment if they are already referenced in the scope that is calling *eval()* (e.g. via a nonlocal statement).

Example:

```
>>> x = 1
>>> eval('x+1')
2
```

This function can also be used to execute arbitrary code objects (such as those created by *compile()*). In this case, pass a code object instead of a string. If the code object has been compiled with 'exec' as the *mode* argument, *eval()*'s return value will be None.

Hints: dynamic execution of statements is supported by the *exec()* function. The *globals()* and *locals()* functions return the current global and local dictionary, respectively, which may be useful to pass around for use by *eval()* or *exec()*.

If the given source is a string, then leading and trailing spaces and tabs are stripped.

See *ast.literal_eval()* for a function that can safely evaluate strings with expressions containing only literals.

Raises an *auditing event* exec with the code object as the argument. Code compilation events may also be raised.

Changed in version 3.13: The *globals* and *locals* arguments can now be passed as keywords.

Changed in version 3.13: The semantics of the default *locals* namespace have been adjusted as described for the *locals()* builtin.

exec(*source*, */*, *globals=None*, *locals=None*, ** (Keyword-only parameters separator (PEP 3102))*, *closure=None*)

> **Warning**
>
> This function executes arbitrary code. Calling it with user-supplied input may lead to security vulnerabilities.

This function supports dynamic execution of Python code. *source* must be either a string or a code object. If it is a string, the string is parsed as a suite of Python statements which is then executed (unless a syntax error occurs).[1] If it is a code object, it is simply executed. In all cases, the code that's executed is expected to be valid as file input (see the section file-input in the Reference Manual). Be aware that the `nonlocal`, `yield`, and `return` statements may not be used outside of function definitions even within the context of code passed to the `exec()` function. The return value is `None`.

In all cases, if the optional parts are omitted, the code is executed in the current scope. If only *globals* is provided, it must be a dictionary (and not a subclass of dictionary), which will be used for both the global and the local variables. If *globals* and *locals* are given, they are used for the global and local variables, respectively. If provided, *locals* can be any mapping object. Remember that at the module level, globals and locals are the same dictionary.

> **Note**
>
> When `exec` gets two separate objects as *globals* and *locals*, the code will be executed as if it were embedded in a class definition. This means functions and classes defined in the executed code will not be able to access variables assigned at the top level (as the "top level" variables are treated as class variables in a class definition).

If the *globals* dictionary does not contain a value for the key `__builtins__`, a reference to the dictionary of the built-in module `builtins` is inserted under that key. That way you can control what builtins are available to the executed code by inserting your own `__builtins__` dictionary into *globals* before passing it to `exec()`.

The *closure* argument specifies a closure–a tuple of cellvars. It's only valid when the *object* is a code object containing *free (closure) variables*. The length of the tuple must exactly match the length of the code object's `co_freevars` attribute.

Raises an *auditing event* `exec` with the code object as the argument. Code compilation events may also be raised.

> **Note**
>
> The built-in functions `globals()` and `locals()` return the current global and local namespace, respectively, which may be useful to pass around for use as the second and third argument to `exec()`.

> **Note**
>
> The default *locals* act as described for function `locals()` below. Pass an explicit *locals* dictionary if you need to see effects of the code on *locals* after function `exec()` returns.

Changed in version 3.11: Added the *closure* parameter.

Changed in version 3.13: The *globals* and *locals* arguments can now be passed as keywords.

Changed in version 3.13: The semantics of the default *locals* namespace have been adjusted as described for the `locals()` builtin.

`filter`(*function*, *iterable*)

Construct an iterator from those elements of *iterable* for which *function* is true. *iterable* may be either a sequence, a container which supports iteration, or an iterator. If *function* is `None`, the identity function is assumed, that is, all elements of *iterable* that are false are removed.

[1] Note that the parser only accepts the Unix-style end of line convention. If you are reading the code from a file, make sure to use newline conversion mode to convert Windows or Mac-style newlines.

Note that `filter(function, iterable)` is equivalent to the generator expression `(item for item in iterable if function(item))` if function is not `None` and `(item for item in iterable if item)` if function is `None`.

See *itertools.filterfalse()* for the complementary function that returns elements of *iterable* for which *function* is false.

class float(*number=0.0*, */*)

class float(*string*, */*)

Return a floating-point number constructed from a number or a string.

Examples:

```
>>> float('+1.23')
1.23
>>> float('   -12345\n')
-12345.0
>>> float('1e-003')
0.001
>>> float('+1E6')
1000000.0
>>> float('-Infinity')
-inf
```

If the argument is a string, it should contain a decimal number, optionally preceded by a sign, and optionally embedded in whitespace. The optional sign may be `'+'` or `'-'`; a `'+'` sign has no effect on the value produced. The argument may also be a string representing a NaN (not-a-number), or positive or negative infinity. More precisely, the input must conform to the *floatvalue* production rule in the following grammar, after leading and trailing whitespace characters are removed:

```
  sign           ::= "+" | "-"
  infinity       ::= "Infinity" | "inf"
  nan            ::= "nan"
  digit          ::= <a Unicode decimal digit, i.e. characters in Unicode gen-
eral category Nd>
  digitpart      ::= digit (["_"] digit)*
  number         ::= [digitpart] "." digitpart | digitpart ["."]
  exponent       ::= ("e" | "E") [sign] digitpart
  floatnumber    ::= number [exponent]
  absfloatvalue ::= floatnumber | infinity | nan
  floatvalue     ::= [sign] absfloatvalue
```

Case is not significant, so, for example, “inf”, “Inf”, “INFINITY”, and “iNfINity” are all acceptable spellings for positive infinity.

Otherwise, if the argument is an integer or a floating-point number, a floating-point number with the same value (within Python’s floating-point precision) is returned. If the argument is outside the range of a Python float, an *OverflowError* will be raised.

For a general Python object `x`, `float(x)` delegates to `x.__float__()`. If `__float__()` is not defined then it falls back to `__index__()`.

If no argument is given, `0.0` is returned.

The float type is described in *Numeric Types — int, float, complex*.

Changed in version 3.6: Grouping digits with underscores as in code literals is allowed.

Changed in version 3.7: The parameter is now positional-only.

Changed in version 3.8: Falls back to `__index__()` if `__float__()` is not defined.

format(*value*, *format_spec=''*)

Convert a *value* to a "formatted" representation, as controlled by *format_spec*. The interpretation of *format_spec* will depend on the type of the *value* argument; however, there is a standard formatting syntax that is used by most built-in types: *Format Specification Mini-Language*.

The default *format_spec* is an empty string which usually gives the same effect as calling `str(value)`.

A call to `format(value, format_spec)` is translated to `type(value).__format__(value, format_spec)` which bypasses the instance dictionary when searching for the value's `__format__()` method. A `TypeError` exception is raised if the method search reaches `object` and the *format_spec* is non-empty, or if either the *format_spec* or the return value are not strings.

Changed in version 3.4: `object().__format__(format_spec)` raises `TypeError` if *format_spec* is not an empty string.

class frozenset(*iterable=set()*)

Return a new `frozenset` object, optionally with elements taken from *iterable*. `frozenset` is a built-in class. See `frozenset` and *Set Types — set, frozenset* for documentation about this class.

For other containers see the built-in `set`, `list`, `tuple`, and `dict` classes, as well as the `collections` module.

getattr(*object*, *name*)

getattr(*object*, *name*, *default*)

Return the value of the named attribute of *object*. *name* must be a string. If the string is the name of one of the object's attributes, the result is the value of that attribute. For example, `getattr(x, 'foobar')` is equivalent to `x.foobar`. If the named attribute does not exist, *default* is returned if provided, otherwise `AttributeError` is raised. *name* need not be a Python identifier (see `setattr()`).

> **Note**
>
> Since private name mangling happens at compilation time, one must manually mangle a private attribute's (attributes with two leading underscores) name in order to retrieve it with `getattr()`.

globals()

Return the dictionary implementing the current module namespace. For code within functions, this is set when the function is defined and remains the same regardless of where the function is called.

hasattr(*object*, *name*)

The arguments are an object and a string. The result is `True` if the string is the name of one of the object's attributes, `False` if not. (This is implemented by calling `getattr(object, name)` and seeing whether it raises an `AttributeError` or not.)

hash(*object*)

Return the hash value of the object (if it has one). Hash values are integers. They are used to quickly compare dictionary keys during a dictionary lookup. Numeric values that compare equal have the same hash value (even if they are of different types, as is the case for 1 and 1.0).

> **Note**
>
> For objects with custom `__hash__()` methods, note that `hash()` truncates the return value based on the bit width of the host machine.

help()

help(*request*)

Invoke the built-in help system. (This function is intended for interactive use.) If no argument is given, the interactive help system starts on the interpreter console. If the argument is a string, then the string is looked up

as the name of a module, function, class, method, keyword, or documentation topic, and a help page is printed on the console. If the argument is any other kind of object, a help page on the object is generated.

Note that if a slash(/) appears in the parameter list of a function when invoking *help()*, it means that the parameters prior to the slash are positional-only. For more info, see the FAQ entry on positional-only parameters.

This function is added to the built-in namespace by the *site* module.

Changed in version 3.4: Changes to *pydoc* and *inspect* mean that the reported signatures for callables are now more comprehensive and consistent.

hex(*x*)

Convert an integer number to a lowercase hexadecimal string prefixed with "0x". If *x* is not a Python *int* object, it has to define an `__index__()` method that returns an integer. Some examples:

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

If you want to convert an integer number to an uppercase or lower hexadecimal string with prefix or not, you can use either of the following ways:

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'{255:#x}', f'{255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

See also *format()* for more information.

See also *int()* for converting a hexadecimal string to an integer using a base of 16.

> **Note**
>
> To obtain a hexadecimal string representation for a float, use the *float.hex()* method.

id(*object*)

Return the "identity" of an object. This is an integer which is guaranteed to be unique and constant for this object during its lifetime. Two objects with non-overlapping lifetimes may have the same *id()* value.

CPython implementation detail: This is the address of the object in memory.

Raises an *auditing event* `builtins.id` with argument `id`.

input()

input(*prompt*)

If the *prompt* argument is present, it is written to standard output without a trailing newline. The function then reads a line from input, converts it to a string (stripping a trailing newline), and returns that. When EOF is read, *EOFError* is raised. Example:

```
>>> s = input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

If the *readline* module was loaded, then *input()* will use it to provide elaborate line editing and history features.

Raises an *auditing event* `builtins.input` with argument `prompt` before reading input

Raises an *auditing event* `builtins.input/result` with the result after successfully reading input.

class int(*number=0*, */*)

class int(*string*, */*, *base=10*)

Return an integer object constructed from a number or a string, or return `0` if no arguments are given.

Examples:

```
>>> int(123.45)
123
>>> int('123')
123
>>> int('   -12_345\n')
-12345
>>> int('FACE', 16)
64206
>>> int('0xface', 0)
64206
>>> int('01110011', base=2)
115
```

If the argument defines `__int__()`, `int(x)` returns `x.__int__()`. If the argument defines `__index__()`, it returns `x.__index__()`. If the argument defines `__trunc__()`, it returns `x.__trunc__()`. For floating-point numbers, this truncates towards zero.

If the argument is not a number or if *base* is given, then it must be a string, *bytes*, or *bytearray* instance representing an integer in radix *base*. Optionally, the string can be preceded by `+` or `-` (with no space in between), have leading zeros, be surrounded by whitespace, and have single underscores interspersed between digits.

A base-n integer string contains digits, each representing a value from 0 to n-1. The values 0–9 can be represented by any Unicode decimal digit. The values 10–35 can be represented by `a` to `z` (or `A` to `Z`). The default *base* is 10. The allowed bases are 0 and 2–36. Base-2, -8, and -16 strings can be optionally prefixed with `0b`/`0B`, `0o`/`0O`, or `0x`/`0X`, as with integer literals in code. For base 0, the string is interpreted in a similar way to an integer literal in code, in that the actual base is 2, 8, 10, or 16 as determined by the prefix. Base 0 also disallows leading zeros: `int('010', 0)` is not legal, while `int('010')` and `int('010', 8)` are.

The integer type is described in *Numeric Types — int, float, complex*.

Changed in version 3.4: If *base* is not an instance of *int* and the *base* object has a `base.__index__` method, that method is called to obtain an integer for the base. Previous versions used `base.__int__` instead of `base.__index__`.

Changed in version 3.6: Grouping digits with underscores as in code literals is allowed.

Changed in version 3.7: The first parameter is now positional-only.

Changed in version 3.8: Falls back to `__index__()` if `__int__()` is not defined.

Changed in version 3.11: The delegation to `__trunc__()` is deprecated.

Changed in version 3.11: *int* string inputs and string representations can be limited to help avoid denial of service attacks. A *ValueError* is raised when the limit is exceeded while converting a string to an *int* or when converting an *int* into a string would exceed the limit. See the *integer string conversion length limitation* documentation.

isinstance(*object*, *classinfo*)

Return `True` if the *object* argument is an instance of the *classinfo* argument, or of a (direct, indirect, or *virtual*) subclass thereof. If *object* is not an object of the given type, the function always returns `False`. If *classinfo* is a

tuple of type objects (or recursively, other such tuples) or a *Union Type* of multiple types, return `True` if *object* is an instance of any of the types. If *classinfo* is not a type or tuple of types and such tuples, a *TypeError* exception is raised. *TypeError* may not be raised for an invalid type if an earlier check succeeds.

Changed in version 3.10: *classinfo* can be a *Union Type*.

issubclass(*class*, *classinfo*)

Return `True` if *class* is a subclass (direct, indirect, or *virtual*) of *classinfo*. A class is considered a subclass of itself. *classinfo* may be a tuple of class objects (or recursively, other such tuples) or a *Union Type*, in which case return `True` if *class* is a subclass of any entry in *classinfo*. In any other case, a *TypeError* exception is raised.

Changed in version 3.10: *classinfo* can be a *Union Type*.

iter(*object*)

iter(*object*, *sentinel*)

Return an *iterator* object. The first argument is interpreted very differently depending on the presence of the second argument. Without a second argument, *object* must be a collection object which supports the *iterable* protocol (the `__iter__()` method), or it must support the sequence protocol (the `__getitem__()` method with integer arguments starting at `0`). If it does not support either of those protocols, *TypeError* is raised. If the second argument, *sentinel*, is given, then *object* must be a callable object. The iterator created in this case will call *object* with no arguments for each call to its *__next__()* method; if the value returned is equal to *sentinel*, *StopIteration* will be raised, otherwise the value will be returned.

See also *Iterator Types*.

One useful application of the second form of *iter()* is to build a block-reader. For example, reading fixed-width blocks from a binary database file until the end of file is reached:

```
from functools import partial
with open('mydata.db', 'rb') as f:
    for block in iter(partial(f.read, 64), b''):
        process_block(block)
```

len(*s*)

Return the length (the number of items) of an object. The argument may be a sequence (such as a string, bytes, tuple, list, or range) or a collection (such as a dictionary, set, or frozen set).

CPython implementation detail: `len` raises *OverflowError* on lengths larger than *sys.maxsize*, such as *range(2 ** 100)*.

class list

class list(*iterable*)

Rather than being a function, *list* is actually a mutable sequence type, as documented in *Lists* and *Sequence Types — list, tuple, range*.

locals()

Return a mapping object representing the current local symbol table, with variable names as the keys, and their currently bound references as the values.

At module scope, as well as when using *exec()* or *eval()* with a single namespace, this function returns the same namespace as *globals()*.

At class scope, it returns the namespace that will be passed to the metaclass constructor.

When using `exec()` or `eval()` with separate local and global arguments, it returns the local namespace passed in to the function call.

In all of the above cases, each call to `locals()` in a given frame of execution will return the *same* mapping object. Changes made through the mapping object returned from `locals()` will be visible as assigned, reassigned, or deleted local variables, and assigning, reassigning, or deleting local variables will immediately affect the contents of the returned mapping object.

In an *optimized scope* (including functions, generators, and coroutines), each call to `locals()` instead returns a fresh dictionary containing the current bindings of the function's local variables and any nonlocal cell references. In this case, name binding changes made via the returned dict are *not* written back to the corresponding local variables or nonlocal cell references, and assigning, reassigning, or deleting local variables and nonlocal cell references does *not* affect the contents of previously returned dictionaries.

Calling `locals()` as part of a comprehension in a function, generator, or coroutine is equivalent to calling it in the containing scope, except that the comprehension's initialised iteration variables will be included. In other scopes, it behaves as if the comprehension were running as a nested function.

Calling `locals()` as part of a generator expression is equivalent to calling it in a nested generator function.

Changed in version 3.12: The behaviour of `locals()` in a comprehension has been updated as described in **PEP 709**.

Changed in version 3.13: As part of **PEP 667**, the semantics of mutating the mapping objects returned from this function are now defined. The behavior in *optimized scopes* is now as described above. Aside from being defined, the behaviour in other scopes remains unchanged from previous versions.

map(*function*, *iterable*, **iterables*)

Return an iterator that applies *function* to every item of *iterable*, yielding the results. If additional *iterables* arguments are passed, *function* must take that many arguments and is applied to the items from all iterables in parallel. With multiple iterables, the iterator stops when the shortest iterable is exhausted. For cases where the function inputs are already arranged into argument tuples, see *itertools.starmap()*.

max(*iterable*, ***, *key=None*)

max(*iterable*, ***, *default*, *key=None*)

max(*arg1*, *arg2*, **args*, *key=None*)

Return the largest item in an iterable or the largest of two or more arguments.

If one positional argument is provided, it should be an *iterable*. The largest item in the iterable is returned. If two or more positional arguments are provided, the largest of the positional arguments is returned.

There are two optional keyword-only arguments. The *key* argument specifies a one-argument ordering function like that used for *list.sort()*. The *default* argument specifies an object to return if the provided iterable is empty. If the iterable is empty and *default* is not provided, a *ValueError* is raised.

If multiple items are maximal, the function returns the first one encountered. This is consistent with other sort-stability preserving tools such as `sorted(iterable, key=keyfunc, reverse=True)[0]` and `heapq.nlargest(1, iterable, key=keyfunc)`.

Changed in version 3.4: Added the *default* keyword-only parameter.

Changed in version 3.8: The *key* can be `None`.

class memoryview(*object*)

Return a "memory view" object created from the given argument. See *Memory Views* for more information.

min(*iterable*, ***, *key=None*)

min(*iterable*, ***, *default*, *key=None*)

min(*arg1*, *arg2*, **args*, *key=None*)

Return the smallest item in an iterable or the smallest of two or more arguments.

If one positional argument is provided, it should be an *iterable*. The smallest item in the iterable is returned. If two or more positional arguments are provided, the smallest of the positional arguments is returned.

There are two optional keyword-only arguments. The *key* argument specifies a one-argument ordering function like that used for *list.sort()*. The *default* argument specifies an object to return if the provided iterable is empty. If the iterable is empty and *default* is not provided, a *ValueError* is raised.

If multiple items are minimal, the function returns the first one encountered. This is consistent with other sort-stability preserving tools such as `sorted(iterable, key=keyfunc)[0]` and `heapq.nsmallest(1, iterable, key=keyfunc)`.

Changed in version 3.4: Added the *default* keyword-only parameter.

Changed in version 3.8: The *key* can be `None`.

next(*iterator*)

next(*iterator*, *default*)

Retrieve the next item from the *iterator* by calling its `__next__()` method. If *default* is given, it is returned if the iterator is exhausted, otherwise `StopIteration` is raised.

class object

This is the ultimate base class of all other classes. It has methods that are common to all instances of Python classes. When the constructor is called, it returns a new featureless object. The constructor does not accept any arguments.

> **Note**
>
> `object` instances do *not* have `__dict__` attributes, so you can't assign arbitrary attributes to an instance of `object`.

oct(*x*)

Convert an integer number to an octal string prefixed with "0o". The result is a valid Python expression. If *x* is not a Python `int` object, it has to define an `__index__()` method that returns an integer. For example:

```
>>> oct(8)
'0o10'
>>> oct(-56)
'-0o70'
```

If you want to convert an integer number to an octal string either with the prefix "0o" or not, you can use either of the following ways.

```
>>> '%#o' % 10, '%o' % 10
('0o12', '12')
>>> format(10, '#o'), format(10, 'o')
('0o12', '12')
>>> f'{10:#o}', f'{10:o}'
('0o12', '12')
```

See also `format()` for more information.

open(*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)

Open *file* and return a corresponding *file object*. If the file cannot be opened, an `OSError` is raised. See tut-files for more examples of how to use this function.

file is a *path-like object* giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed unless *closefd* is set to `False`.)

mode is an optional string that specifies the mode in which the file is opened. It defaults to `'r'` which means open for reading in text mode. Other common values are `'w'` for writing (truncating the file if it already exists), `'x'` for exclusive creation, and `'a'` for appending (which on *some* Unix systems, means that *all* writes append to the end of the file regardless of the current seek position). In text mode, if *encoding* is not specified the encoding used is platform-dependent: `locale.getencoding()` is called to get the current locale encoding. (For reading and writing raw bytes use binary mode and leave *encoding* unspecified.) The available modes are:

Character	Meaning
`'r'`	open for reading (default)
`'w'`	open for writing, truncating the file first
`'x'`	open for exclusive creation, failing if the file already exists
`'a'`	open for writing, appending to the end of file if it exists
`'b'`	binary mode
`'t'`	text mode (default)
`'+'`	open for updating (reading and writing)

The default mode is `'r'` (open for reading text, a synonym of `'rt'`). Modes `'w+'` and `'w+b'` open and truncate the file. Modes `'r+'` and `'r+b'` open the file with no truncation.

As mentioned in the *Overview*, Python distinguishes between binary and text I/O. Files opened in binary mode (including `'b'` in the *mode* argument) return contents as *bytes* objects without any decoding. In text mode (the default, or when `'t'` is included in the *mode* argument), the contents of the file are returned as *str*, the bytes having been first decoded using a platform-dependent encoding or using the specified *encoding* if given.

Note

Python doesn't depend on the underlying operating system's notion of text files; all the processing is done by Python itself, and is therefore platform-independent.

buffering is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable when writing in text mode), and an integer > 1 to indicate the size in bytes of a fixed-size chunk buffer. Note that specifying a buffer size this way applies for binary buffered I/O, but `TextIOWrapper` (i.e., files opened with `mode='r+'`) would have another buffering. To disable buffering in `TextIOWrapper`, consider using the `write_through` flag for *io.TextIOWrapper.reconfigure()*. When no *buffering* argument is given, the default buffering policy works as follows:

- Binary files are buffered in fixed-size chunks; the size of the buffer is chosen using a heuristic trying to determine the underlying device's "block size" and falling back on *io.DEFAULT_BUFFER_SIZE*. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- "Interactive" text files (files for which *isatty()* returns `True`) use line buffering. Other text files use the policy described above for binary files.

encoding is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever *locale.getencoding()* returns), but any *text encoding* supported by Python can be used. See the *codecs* module for the list of supported encodings.

errors is an optional string that specifies how encoding and decoding errors are to be handled—this cannot be used in binary mode. A variety of standard error handlers are available (listed under *Error Handlers*), though any error handling name that has been registered with *codecs.register_error()* is also valid. The standard names include:

- `'strict'` to raise a *ValueError* exception if there is an encoding error. The default value of `None` has the same effect.
- `'ignore'` ignores errors. Note that ignoring encoding errors can lead to data loss.
- `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data.
- `'surrogateescape'` will represent any incorrect bytes as low surrogate code units ranging from U+DC80 to U+DCFF. These surrogate code units will then be turned back into the same bytes when the `surrogateescape` error handler is used when writing data. This is useful for processing files in an unknown encoding.
- `'xmlcharrefreplace'` is only supported when writing to a file. Characters not supported by the encoding are replaced with the appropriate XML character reference `&#`*nnn*`;`.
- `'backslashreplace'` replaces malformed data by Python's backslashed escape sequences.

- `'namereplace'` (also only supported when writing) replaces unsupported characters with `\N{...}` escape sequences.

newline determines how to parse newline characters from the stream. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, universal newlines mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, *os.linesep*. If *newline* is `''` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *closefd* is `False` and a file descriptor rather than a filename was given, the underlying file descriptor will be kept open when the file is closed. If a filename is given *closefd* must be `True` (the default); otherwise, an error will be raised.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*file*, *flags*). *opener* must return an open file descriptor (passing *os.open* as *opener* results in functionality similar to passing `None`).

The newly created file is *non-inheritable*.

The following example uses the *dir_fd* parameter of the *os.open()* function to open a file relative to a given directory:

```
>>> import os
>>> dir_fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
...     return os.open(path, flags, dir_fd=dir_fd)
...
>>> with open('spamspam.txt', 'w', opener=opener) as f:
...     print('This will be written to somedir/spamspam.txt', file=f)
...
>>> os.close(dir_fd)  # don't leak a file descriptor
```

The type of *file object* returned by the *open()* function depends on the mode. When *open()* is used to open a file in a text mode (`'w'`, `'r'`, `'wt'`, `'rt'`, etc.), it returns a subclass of *io.TextIOBase* (specifically *io.TextIOWrapper*). When used to open a file in a binary mode with buffering, the returned class is a subclass of *io.BufferedIOBase*. The exact class varies: in read binary mode, it returns an *io.BufferedReader*; in write binary and append binary modes, it returns an *io.BufferedWriter*, and in read/write mode, it returns an *io.BufferedRandom*. When buffering is disabled, the raw stream, a subclass of *io.RawIOBase*, *io.FileIO*, is returned.

See also the file handling modules, such as *fileinput*, *io* (where *open()* is declared), *os*, *os.path*, *tempfile*, and *shutil*.

Raises an *auditing event* `open` with arguments `path`, `mode`, `flags`.

The `mode` and `flags` arguments may have been modified or inferred from the original call.

Changed in version 3.3:

- The *opener* parameter was added.
- The `'x'` mode was added.
- *IOError* used to be raised, it is now an alias of *OSError*.
- *FileExistsError* is now raised if the file opened in exclusive creation mode (`'x'`) already exists.

Changed in version 3.4:

- The file is now non-inheritable.

Changed in version 3.5:

- If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).
- The `'namereplace'` error handler was added.

Changed in version 3.6:

- Support added to accept objects implementing *os.PathLike*.
- On Windows, opening a console buffer may return a subclass of *io.RawIOBase* other than *io.FileIO*.

Changed in version 3.11: The `'U'` mode has been removed.

ord(*c*)

Given a string representing one Unicode character, return an integer representing the Unicode code point of that character. For example, `ord('a')` returns the integer `97` and `ord('€')` (Euro sign) returns `8364`. This is the inverse of *chr()*.

pow(*base*, *exp*, *mod=None*)

Return *base* to the power *exp*; if *mod* is present, return *base* to the power *exp*, modulo *mod* (computed more efficiently than `pow(base, exp) % mod`). The two-argument form `pow(base, exp)` is equivalent to using the power operator: `base**exp`.

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For *int* operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, `pow(10, 2)` returns `100`, but `pow(10, -2)` returns `0.01`. For a negative base of type *int* or *float* and a non-integral exponent, a complex result is delivered. For example, `pow(-9, 0.5)` returns a value close to `3j`. Whereas, for a negative base of type *int* or *float* with an integral exponent, a float result is delivered. For example, `pow(-9, 2.0)` returns `81.0`.

For *int* operands *base* and *exp*, if *mod* is present, *mod* must also be of integer type and *mod* must be nonzero. If *mod* is present and *exp* is negative, *base* must be relatively prime to *mod*. In that case, `pow(inv_base, -exp, mod)` is returned, where *inv_base* is an inverse to *base* modulo *mod*.

Here's an example of computing an inverse for `38` modulo `97`:

```
>>> pow(38, -1, mod=97)
23
>>> 23 * 38 % 97 == 1
True
```

Changed in version 3.8: For *int* operands, the three-argument form of `pow` now allows the second argument to be negative, permitting computation of modular inverses.

Changed in version 3.8: Allow keyword arguments. Formerly, only positional arguments were supported.

print(**objects*, *sep=' '*, *end='\n'*, *file=None*, *flush=False*)

Print *objects* to the text stream *file*, separated by *sep* and followed by *end*. *sep*, *end*, *file*, and *flush*, if present, must be given as keyword arguments.

All non-keyword arguments are converted to strings like *str()* does and written to the stream, separated by *sep* and followed by *end*. Both *sep* and *end* must be strings; they can also be `None`, which means to use the default values. If no *objects* are given, *print()* will just write *end*.

The *file* argument must be an object with a `write(string)` method; if it is not present or `None`, *sys.stdout* will be used. Since printed arguments are converted to text strings, *print()* cannot be used with binary mode file objects. For these, use `file.write(...)` instead.

Output buffering is usually determined by *file*. However, if *flush* is true, the stream is forcibly flushed.

Changed in version 3.3: Added the *flush* keyword argument.

class property(*fget=None*, *fset=None*, *fdel=None*, *doc=None*)

Return a property attribute.

fget is a function for getting an attribute value. *fset* is a function for setting an attribute value. *fdel* is a function for deleting an attribute value. And *doc* creates a docstring for the attribute.

A typical use is to define a managed attribute `x`:

```
class C:
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

    x = property(getx, setx, delx, "I'm the 'x' property.")
```

If *c* is an instance of *C*, `c.x` will invoke the getter, `c.x = value` will invoke the setter, and `del c.x` the deleter.

If given, *doc* will be the docstring of the property attribute. Otherwise, the property will copy *fget*'s docstring (if it exists). This makes it possible to create read-only properties easily using *property()* as a *decorator*:

```
class Parrot:
    def __init__(self):
        self._voltage = 100000

    @property
    def voltage(self):
        """Get the current voltage."""
        return self._voltage
```

The `@property` decorator turns the `voltage()` method into a "getter" for a read-only attribute with the same name, and it sets the docstring for *voltage* to "Get the current voltage."

@getter

@setter

@deleter

A property object has `getter`, `setter`, and `deleter` methods usable as decorators that create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

```
class C:
    def __init__(self):
        self._x = None

    @property
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
```

(continues on next page)

(continued from previous page)

```
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x
```

This code is exactly equivalent to the first example. Be sure to give the additional functions the same name as the original property (`x` in this case.)

The returned property object also has the attributes `fget`, `fset`, and `fdel` corresponding to the constructor arguments.

Changed in version 3.5: The docstrings of property objects are now writeable.

__name__

Attribute holding the name of the property. The name of the property can be changed at runtime.

Added in version 3.13.

class range(*stop*)

class range(*start*, *stop*, *step=1*)

Rather than being a function, *range* is actually an immutable sequence type, as documented in *Ranges* and *Sequence Types — list, tuple, range*.

repr(*object*)

Return a string containing a printable representation of an object. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to *eval()*; otherwise, the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method. If *sys.displayhook()* is not accessible, this function will raise *RuntimeError*.

This class has a custom representation that can be evaluated:

```
class Person:
   def __init__(self, name, age):
      self.name = name
      self.age = age

   def __repr__(self):
      return f"Person('{self.name}', {self.age})"
```

reversed(*seq*)

Return a reverse *iterator*. *seq* must be an object which has a `__reversed__()` method or supports the sequence protocol (the `__len__()` method and the `__getitem__()` method with integer arguments starting at `0`).

round(*number*, *ndigits=None*)

Return *number* rounded to *ndigits* precision after the decimal point. If *ndigits* is omitted or is `None`, it returns the nearest integer to its input.

For the built-in types supporting *round()*, values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done toward the even choice (so, for example, both `round(0.5)` and `round(-0.5)` are `0`, and `round(1.5)` is `2`). Any integer value is valid for *ndigits* (positive, zero, or negative). The return value is an integer if *ndigits* is omitted or `None`. Otherwise, the return value has the same type as *number*.

For a general Python object `number`, `round` delegates to `number.__round__`.

> **Note**
>
> The behavior of *round()* for floats can be surprising: for example, `round(2.675, 2)` gives `2.67` instead of the expected `2.68`. This is not a bug: it's a result of the fact that most decimal fractions can't be represented exactly as a float. See tut-fp-issues for more information.

class set

class set(*iterable*)

Return a new *set* object, optionally with elements taken from *iterable*. `set` is a built-in class. See *set* and *Set Types — set, frozenset* for documentation about this class.

For other containers see the built-in *frozenset*, *list*, *tuple*, and *dict* classes, as well as the *collections* module.

setattr(*object*, *name*, *value*)

This is the counterpart of *getattr()*. The arguments are an object, a string, and an arbitrary value. The string may name an existing attribute or a new attribute. The function assigns the value to the attribute, provided the object allows it. For example, `setattr(x, 'foobar', 123)` is equivalent to `x.foobar = 123`.

name need not be a Python identifier as defined in identifiers unless the object chooses to enforce that, for example in a custom `__getattribute__()` or via `__slots__`. An attribute whose name is not an identifier will not be accessible using the dot notation, but is accessible through *getattr()* etc..

> **Note**
>
> Since private name mangling happens at compilation time, one must manually mangle a private attribute's (attributes with two leading underscores) name in order to set it with *setattr()*.

class slice(*stop*)

class slice(*start*, *stop*, *step=None*)

Return a *slice* object representing the set of indices specified by `range(start, stop, step)`. The *start* and *step* arguments default to `None`.

start

stop

step

Slice objects have read-only data attributes `start`, `stop`, and `step` which merely return the argument values (or their default). They have no other explicit functionality; however, they are used by NumPy and other third-party packages.

Slice objects are also generated when extended indexing syntax is used. For example: `a[start:stop:step]` or `a[start:stop, i]`. See *itertools.islice()* for an alternate version that returns an *iterator*.

Changed in version 3.12: Slice objects are now *hashable* (provided *start*, *stop*, and *step* are hashable).

sorted(*iterable*, */*, *, *key=None*, *reverse=False*)

Return a new sorted list from the items in *iterable*.

Has two optional arguments which must be specified as keyword arguments.

key specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). The default value is `None` (compare the elements directly).

reverse is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

Use *functools.cmp_to_key()* to convert an old-style *cmp* function to a *key* function.

The built-in *sorted()* function is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

The sort algorithm uses only < comparisons between items. While defining an `__lt__()` method will suffice for sorting, **PEP 8** recommends that all six rich comparisons be implemented. This will help avoid bugs when using the same data with other ordering tools such as *max()* that rely on a different underlying method. Implementing all six comparisons also helps avoid confusion for mixed type comparisons which can call reflected the `__gt__()` method.

For sorting examples and a brief sorting tutorial, see sortinghowto.

@staticmethod

Transform a method into a static method.

A static method does not receive an implicit first argument. To declare a static method, use this idiom:

```
class C:
    @staticmethod
    def f(arg1, arg2, argN): ...
```

The `@staticmethod` form is a function *decorator* – see function for details.

A static method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). Moreover, the static method *descriptor* is also callable, so it can be used in the class definition (such as `f()`).

Static methods in Python are similar to those found in Java or C++. Also, see *classmethod()* for a variant that is useful for creating alternate class constructors.

Like all decorators, it is also possible to call `staticmethod` as a regular function and do something with its result. This is needed in some cases where you need a reference to a function from a class body and you want to avoid the automatic transformation to instance method. For these cases, use this idiom:

```
def regular_function():
    ...

class C:
    method = staticmethod(regular_function)
```

For more information on static methods, see types.

Changed in version 3.10: Static methods now inherit the method attributes (`__module__`, `__name__`, `__qualname__`, `__doc__` and `__annotations__`), have a new `__wrapped__` attribute, and are now callable as regular functions.

class str(*object=''*)

class str(*object=b''*, *encoding='utf-8'*, *errors='strict'*)

Return a *str* version of *object*. See *str()* for details.

`str` is the built-in string *class*. For general information about strings, see *Text Sequence Type — str*.

sum(*iterable*, */*, *start=0*)

Sums *start* and the items of an *iterable* from left to right and returns the total. The *iterable*'s items are normally numbers, and the start value is not allowed to be a string.

For some use cases, there are good alternatives to *sum()*. The preferred, fast way to concatenate a sequence of strings is by calling `''.join(sequence)`. To add floating-point values with extended precision, see *math.fsum()*. To concatenate a series of iterables, consider using *itertools.chain()*.

Changed in version 3.8: The *start* parameter can be specified as a keyword argument.

Changed in version 3.12: Summation of floats switched to an algorithm that gives higher accuracy and better commutativity on most builds.

class super

class super(*type*, *object_or_type=None*)

Return a proxy object that delegates method calls to a parent or sibling class of *type*. This is useful for accessing inherited methods that have been overridden in a class.

The *object_or_type* determines the *method resolution order* to be searched. The search starts from the class right after the *type*.

For example, if `__mro__` of *object_or_type* is `D -> B -> C -> A -> object` and the value of *type* is `B`, then *super()* searches `C -> A -> object`.

The `__mro__` attribute of the class corresponding to *object_or_type* lists the method resolution search order used by both *getattr()* and *super()*. The attribute is dynamic and can change whenever the inheritance hierarchy is updated.

If the second argument is omitted, the super object returned is unbound. If the second argument is an object, `isinstance(obj, type)` must be true. If the second argument is a type, `issubclass(type2, type)` must be true (this is useful for classmethods).

When called directly within an ordinary method of a class, both arguments may be omitted ("zero-argument `super()`"). In this case, *type* will be the enclosing class, and *obj* will be the first argument of the immediately enclosing function (typically `self`). (This means that zero-argument `super()` will not work as expected within nested functions, including generator expressions, which implicitly create nested functions.)

There are two typical use cases for *super*. In a class hierarchy with single inheritance, *super* can be used to refer to parent classes without naming them explicitly, thus making the code more maintainable. This use closely parallels the use of *super* in other programming languages.

The second use case is to support cooperative multiple inheritance in a dynamic execution environment. This use case is unique to Python and is not found in statically compiled languages or languages that only support single inheritance. This makes it possible to implement "diamond diagrams" where multiple base classes implement the same method. Good design dictates that such implementations have the same calling signature in every case (because the order of calls is determined at runtime, because that order adapts to changes in the class hierarchy, and because that order can include sibling classes that are unknown prior to runtime).

For both use cases, a typical superclass call looks like this:

```
class C(B):
    def method(self, arg):
        super().method(arg)     # This does the same thing as:
                                # super(C, self).method(arg)
```

In addition to method lookups, *super()* also works for attribute lookups. One possible use case for this is calling *descriptors* in a parent or sibling class.

Note that *super()* is implemented as part of the binding process for explicit dotted attribute lookups such as `super().__getitem__(name)`. It does so by implementing its own `__getattribute__()` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, *super()* is undefined for implicit lookups using statements or operators such as `super()[name]`.

Also note that, aside from the zero argument form, *super()* is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references. The zero argument form only works inside a class definition, as the compiler fills in the necessary details to correctly retrieve the class being defined, as well as accessing the current instance for ordinary methods.

For practical suggestions on how to design cooperative classes using *super()*, see guide to using super().

class tuple

class tuple(*iterable*)

Rather than being a function, *tuple* is actually an immutable sequence type, as documented in *Tuples* and *Sequence Types — list, tuple, range*.

class type(*object*)

class type(*name*, *bases*, *dict*, ***kwds*)

With one argument, return the type of an *object*. The return value is a type object and generally the same object as returned by `object.__class__`.

The *isinstance()* built-in function is recommended for testing the type of an object, because it takes subclasses into account.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute. The *bases* tuple contains the base classes and becomes the `__bases__` attribute; if empty, *object*, the ultimate base of all classes, is added. The *dict* dictionary contains attribute and method definitions for the class body; it may be copied or wrapped before becoming the `__dict__` attribute. The following two statements create identical `type` objects:

```
>>> class X:
...     a = 1
...
>>> X = type('X', (), dict(a=1))
```

See also:

- Documentation on attributes and methods on classes.
- *Type Objects*

Keyword arguments provided to the three argument form are passed to the appropriate metaclass machinery (usually `__init_subclass__()`) in the same way that keywords in a class definition (besides *metaclass*) would.

See also class-customization.

Changed in version 3.6: Subclasses of `type` which don't override `type.__new__` may no longer use the one-argument form to get the type of an object.

vars()

vars(*object*)

Return the `__dict__` attribute for a module, class, instance, or any other object with a `__dict__` attribute.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, classes use a *types.MappingProxyType* to prevent direct dictionary updates).

Without an argument, *vars()* acts like *locals()*.

A *TypeError* exception is raised if an object is specified but it doesn't have a `__dict__` attribute (for example, if its class defines the `__slots__` attribute).

Changed in version 3.13: The result of calling this function without an argument has been updated as described for the *locals()* builtin.

zip(**iterables*, *strict=False*)

Iterate over several iterables in parallel, producing tuples with an item from each one.

Example:

```
>>> for item in zip([1, 2, 3], ['sugar', 'spice', 'everything nice']):
...     print(item)
...
(1, 'sugar')
(2, 'spice')
(3, 'everything nice')
```

More formally: *zip()* returns an iterator of tuples, where the *i*-th tuple contains the *i*-th element from each of the argument iterables.

Another way to think of *zip()* is that it turns rows into columns, and columns into rows. This is similar to transposing a matrix.

zip() is lazy: The elements won't be processed until the iterable is iterated on, e.g. by a `for` loop or by wrapping in a *list*.

One thing to consider is that the iterables passed to *zip()* could have different lengths; sometimes by design, and sometimes because of a bug in the code that prepared these iterables. Python offers three different approaches to dealing with this issue:

- By default, *zip()* stops when the shortest iterable is exhausted. It will ignore the remaining items in the longer iterables, cutting off the result to the length of the shortest iterable:

```
>>> list(zip(range(3), ['fee', 'fi', 'fo', 'fum']))
[(0, 'fee'), (1, 'fi'), (2, 'fo')]
```

- *zip()* is often used in cases where the iterables are assumed to be of equal length. In such cases, it's recommended to use the `strict=True` option. Its output is the same as regular *zip()*:

```
>>> list(zip(('a', 'b', 'c'), (1, 2, 3), strict=True))
[('a', 1), ('b', 2), ('c', 3)]
```

  Unlike the default behavior, it raises a *ValueError* if one iterable is exhausted before the others:

```
>>> for item in zip(range(3), ['fee', 'fi', 'fo', 'fum'], strict=True):
...     print(item)
...
(0, 'fee')
(1, 'fi')
(2, 'fo')
Traceback (most recent call last):
  ...
ValueError: zip() argument 2 is longer than argument 1
```

  Without the `strict=True` argument, any bug that results in iterables of different lengths will be silenced, possibly manifesting as a hard-to-find bug in another part of the program.

- Shorter iterables can be padded with a constant value to make all the iterables have the same length. This is done by *itertools.zip_longest()*.

Edge cases: With a single iterable argument, *zip()* returns an iterator of 1-tuples. With no arguments, it returns an empty iterator.

Tips and tricks:

- The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using `zip(*[iter(s)]*n, strict=True)`. This repeats the *same* iterator `n` times so that each output tuple has the result of `n` calls to the iterator. This has the effect of dividing the input into n-length chunks.

- *zip()* in conjunction with the `*` operator can be used to unzip a list:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> list(zip(x, y))
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zip(x, y))
>>> x == list(x2) and y == list(y2)
True
```

Changed in version 3.10: Added the `strict` argument.

__import__(*name*, *globals=None*, *locals=None*, *fromlist=()*, *level=0*)

> **Note**
>
> This is an advanced function that is not needed in everyday Python programming, unlike *importlib.import_module()*.

This function is invoked by the `import` statement. It can be replaced (by importing the *builtins* module and assigning to `builtins.__import__`) in order to change semantics of the `import` statement, but doing so is **strongly** discouraged as it is usually simpler to use import hooks (see **PEP 302**) to attain the same goals and does not cause issues with code which assumes the default import implementation is in use. Direct use of *__import__()* is also discouraged in favor of *importlib.import_module()*.

The function imports the module *name*, potentially using the given *globals* and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be imported from the module given by *name*. The standard implementation does not use its *locals* argument at all and uses its *globals* only to determine the package context of the `import` statement.

level specifies whether to use absolute or relative imports. `0` (the default) means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling *__import__()* (see **PEP 328** for the details).

When the *name* variable is of the form `package.module`, normally, the top-level package (the name up till the first dot) is returned, *not* the module named by *name*. However, when a non-empty *fromlist* argument is given, the module named by *name* is returned.

For example, the statement `import spam` results in bytecode resembling the following code:

```
spam = __import__('spam', globals(), locals(), [], 0)
```

The statement `import spam.ham` results in this call:

```
spam = __import__('spam.ham', globals(), locals(), [], 0)
```

Note how *__import__()* returns the toplevel module here because this is the object that is bound to a name by the `import` statement.

On the other hand, the statement `from spam.ham import eggs, sausage as saus` results in

```
_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], 0)
eggs = _temp.eggs
saus = _temp.sausage
```

Here, the `spam.ham` module is returned from *__import__()*. From this object, the names to import are retrieved and assigned to their respective names.

If you simply want to import a module (potentially within a package) by name, use *importlib.import_module()*.

Changed in version 3.3: Negative values for *level* are no longer supported (which also changes the default value to 0).

Changed in version 3.9: When the command line options `-E` or `-I` are being used, the environment variable `PYTHONCASEOK` is now ignored.

CHAPTER

THREE

BUILT-IN CONSTANTS

A small number of constants live in the built-in namespace. They are:

False

The false value of the *bool* type. Assignments to `False` are illegal and raise a *SyntaxError*.

True

The true value of the *bool* type. Assignments to `True` are illegal and raise a *SyntaxError*.

None

An object frequently used to represent the absence of a value, as when default arguments are not passed to a function. Assignments to `None` are illegal and raise a *SyntaxError*. `None` is the sole instance of the *NoneType* type.

NotImplemented

A special value which should be returned by the binary special methods (e.g. `__eq__()`, `__lt__()`, `__add__()`, `__rsub__()`, etc.) to indicate that the operation is not implemented with respect to the other type; may be returned by the in-place binary special methods (e.g. `__imul__()`, `__iand__()`, etc.) for the same purpose. It should not be evaluated in a boolean context. `NotImplemented` is the sole instance of the *types.NotImplementedType* type.

> **Note**
>
> When a binary (or in-place) method returns `NotImplemented` the interpreter will try the reflected operation on the other type (or some other fallback, depending on the operator). If all attempts return `NotImplemented`, the interpreter will raise an appropriate exception. Incorrectly returning `NotImplemented` will result in a misleading error message or the `NotImplemented` value being returned to Python code.
>
> See *Implementing the arithmetic operations* for examples.

> **Caution**
>
> `NotImplemented` and `NotImplementedError` are not interchangeable. This constant should only be used as described above; see *NotImplementedError* for details on correct usage of the exception.

Changed in version 3.9: Evaluating `NotImplemented` in a boolean context is deprecated. While it currently evaluates as true, it will emit a *DeprecationWarning*. It will raise a *TypeError* in a future version of Python.

Ellipsis

The same as the ellipsis literal "`...`". Special value used mostly in conjunction with extended slicing syntax for user-defined container data types. `Ellipsis` is the sole instance of the *types.EllipsisType* type.

__debug__

This constant is true if Python was not started with an `-O` option. See also the `assert` statement.

Note

The names *None*, *False*, *True* and *__debug__* cannot be reassigned (assignments to them, even as an attribute name, raise *SyntaxError*), so they can be considered "true" constants.

3.1 Constants added by the site module

The *site* module (which is imported automatically during startup, except if the `-S` command-line option is given) adds several constants to the built-in namespace. They are useful for the interactive interpreter shell and should not be used in programs.

quit(*code=None*)

exit(*code=None*)

Objects that when printed, print a message like "Use quit() or Ctrl-D (i.e. EOF) to exit", and when called, raise *SystemExit* with the specified exit code.

help

Object that when printed, prints the message "Type help() for interactive help, or help(object) for help about object.", and when called, acts as described *elsewhere*.

copyright

credits

Objects that when printed or called, print the text of copyright or credits, respectively.

license

Object that when printed, prints the message "Type license() to see the full license text", and when called, displays the full license text in a pager-like fashion (one screen at a time).

CHAPTER

FOUR

BUILT-IN TYPES

The following sections describe the standard types that are built into the interpreter.

The principal built-in types are numerics, sequences, mappings, classes, instances and exceptions.

Some collection classes are mutable. The methods that add, subtract, or rearrange their members in place, and don't return a specific item, never return the collection instance itself but `None`.

Some operations are supported by several object types; in particular, practically all objects can be compared for equality, tested for truth value, and converted to a string (with the *`repr()`* function or the slightly different *`str()`* function). The latter function is implicitly used when an object is written by the *`print()`* function.

4.1 Truth Value Testing

Any object can be tested for truth value, for use in an `if` or `while` condition or as operand of the Boolean operations below.

By default, an object is considered true unless its class defines either a `__bool__()` method that returns `False` or a `__len__()` method that returns zero, when called with the object.[1] Here are most of the built-in objects considered false:

- constants defined to be false: `None` and `False`
- zero of any numeric type: `0`, `0.0`, `0j`, `Decimal(0)`, `Fraction(0, 1)`
- empty sequences and collections: `''`, `()`, `[]`, `{}`, `set()`, `range(0)`

Operations and built-in functions that have a Boolean result always return `0` or `False` for false and `1` or `True` for true, unless otherwise stated. (Important exception: the Boolean operations `or` and `and` always return one of their operands.)

4.2 Boolean Operations — `and`, `or`, `not`

These are the Boolean operations, ordered by ascending priority:

Operation	Result	Notes
`x or y`	if *x* is true, then *x*, else *y*	(1)
`x and y`	if *x* is false, then *x*, else *y*	(2)
`not x`	if *x* is false, then `True`, else `False`	(3)

Notes:

(1) This is a short-circuit operator, so it only evaluates the second argument if the first one is false.

(2) This is a short-circuit operator, so it only evaluates the second argument if the first one is true.

[1] Additional information on these special methods may be found in the Python Reference Manual (customization).

(3) `not` has a lower priority than non-Boolean operators, so `not a == b` is interpreted as `not (a == b)`, and `a == not b` is a syntax error.

4.3 Comparisons

There are eight comparison operations in Python. They all have the same priority (which is higher than that of the Boolean operations). Comparisons can be chained arbitrarily; for example, `x < y <= z` is equivalent to `x < y and y <= z`, except that *y* is evaluated only once (but in both cases *z* is not evaluated at all when `x < y` is found to be false).

This table summarizes the comparison operations:

Operation	Meaning
`<`	strictly less than
`<=`	less than or equal
`>`	strictly greater than
`>=`	greater than or equal
`==`	equal
`!=`	not equal
`is`	object identity
`is not`	negated object identity

Objects of different types, except different numeric types, never compare equal. The == operator is always defined but for some object types (for example, class objects) is equivalent to `is`. The <, <=, > and >= operators are only defined where they make sense; for example, they raise a *TypeError* exception when one of the arguments is a complex number.

Non-identical instances of a class normally compare as non-equal unless the class defines the `__eq__()` method.

Instances of a class cannot be ordered with respect to other instances of the same class, or other types of object, unless the class defines enough of the methods `__lt__()`, `__le__()`, `__gt__()`, and `__ge__()` (in general, `__lt__()` and `__eq__()` are sufficient, if you want the conventional meanings of the comparison operators).

The behavior of the `is` and `is not` operators cannot be customized; also they can be applied to any two objects and never raise an exception.

Two more operations with the same syntactic priority, `in` and `not in`, are supported by types that are *iterable* or implement the `__contains__()` method.

4.4 Numeric Types — `int`, `float`, `complex`

There are three distinct numeric types: *integers*, *floating-point numbers*, and *complex numbers*. In addition, Booleans are a subtype of integers. Integers have unlimited precision. Floating-point numbers are usually implemented using `double` in C; information about the precision and internal representation of floating-point numbers for the machine on which your program is running is available in *sys.float_info*. Complex numbers have a real and imaginary part, which are each a floating-point number. To extract these parts from a complex number *z*, use `z.real` and `z.imag`. (The standard library includes the additional numeric types *fractions.Fraction*, for rationals, and *decimal.Decimal*, for floating-point numbers with user-definable precision.)

Numbers are created by numeric literals or as the result of built-in functions and operators. Unadorned integer literals (including hex, octal and binary numbers) yield integers. Numeric literals containing a decimal point or an exponent sign yield floating-point numbers. Appending `'j'` or `'J'` to a numeric literal yields an imaginary number (a complex number with a zero real part) which you can add to an integer or float to get a complex number with real and imaginary parts.

Python fully supports mixed arithmetic: when a binary arithmetic operator has operands of different numeric types, the operand with the "narrower" type is widened to that of the other, where integer is narrower than floating point,

which is narrower than complex. A comparison between numbers of different types behaves as though the exact values of those numbers were being compared.[2]

The constructors *int()*, *float()*, and *complex()* can be used to produce numbers of a specific type.

All numeric types (except complex) support the following operations (for priorities of the operations, see operator-summary):

Operation	Result	Notes	Full documentation
`x + y`	sum of *x* and *y*		
`x - y`	difference of *x* and *y*		
`x * y`	product of *x* and *y*		
`x / y`	quotient of *x* and *y*		
`x // y`	floored quotient of *x* and *y*	(1)(2)	
`x % y`	remainder of `x / y`	(2)	
`-x`	*x* negated		
`+x`	*x* unchanged		
`abs(x)`	absolute value or magnitude of *x*		*abs()*
`int(x)`	*x* converted to integer	(3)(6)	*int()*
`float(x)`	*x* converted to floating point	(4)(6)	*float()*
`complex(re, im)`	a complex number with real part *re*, imaginary part *im*. *im* defaults to zero.	(6)	*complex()*
`c.conjugate()`	conjugate of the complex number *c*		
`divmod(x, y)`	the pair `(x // y, x % y)`	(2)	*divmod()*
`pow(x, y)`	*x* to the power *y*	(5)	*pow()*
`x ** y`	*x* to the power *y*	(5)	

Notes:

(1) Also referred to as integer division. For operands of type *int*, the result has type *int*. For operands of type *float*, the result has type *float*. In general, the result is a whole integer, though the result's type is not necessarily *int*. The result is always rounded towards minus infinity: `1//2` is `0`, `(-1)//2` is `-1`, `1//(-2)` is `-1`, and `(-1)//(-2)` is `0`.

(2) Not for complex numbers. Instead convert to floats using *abs()* if appropriate.

(3) Conversion from *float* to *int* truncates, discarding the fractional part. See functions *math.floor()* and *math.ceil()* for alternative conversions.

(4) float also accepts the strings "nan" and "inf" with an optional prefix "+" or "-" for Not a Number (NaN) and positive or negative infinity.

(5) Python defines `pow(0, 0)` and `0 ** 0` to be `1`, as is common for programming languages.

(6) The numeric literals accepted include the digits `0` to `9` or any Unicode equivalent (code points with the `Nd` property).

See the Unicode Standard for a complete list of code points with the `Nd` property.

All *numbers.Real* types (*int* and *float*) also include the following operations:

Operation	Result
math.trunc(x)	*x* truncated to *Integral*
round(x[, n])	*x* rounded to *n* digits, rounding half to even. If *n* is omitted, it defaults to 0.
math.floor(x)	the greatest *Integral* <= *x*
math.ceil(x)	the least *Integral* >= *x*

[2] As a consequence, the list `[1, 2]` is considered equal to `[1.0, 2.0]`, and similarly for tuples.

For additional numeric operations see the *math* and *cmath* modules.

4.4.1 Bitwise Operations on Integer Types

Bitwise operations only make sense for integers. The result of bitwise operations is calculated as though carried out in two's complement with an infinite number of sign bits.

The priorities of the binary bitwise operations are all lower than the numeric operations and higher than the comparisons; the unary operation `~` has the same priority as the other unary numeric operations (`+` and `-`).

This table lists the bitwise operations sorted in ascending priority:

Operation	Result	Notes
`x | y`	bitwise *or* of *x* and *y*	(4)
`x ^ y`	bitwise *exclusive or* of *x* and *y*	(4)
`x & y`	bitwise *and* of *x* and *y*	(4)
`x << n`	*x* shifted left by *n* bits	(1)(2)
`x >> n`	*x* shifted right by *n* bits	(1)(3)
`~x`	the bits of *x* inverted	

Notes:

(1) Negative shift counts are illegal and cause a *ValueError* to be raised.

(2) A left shift by *n* bits is equivalent to multiplication by `pow(2, n)`.

(3) A right shift by *n* bits is equivalent to floor division by `pow(2, n)`.

(4) Performing these calculations with at least one extra sign extension bit in a finite two's complement representation (a working bit-width of `1 + max(x.bit_length(), y.bit_length())` or more) is sufficient to get the same result as if there were an infinite number of sign bits.

4.4.2 Additional Methods on Integer Types

The int type implements the *numbers.Integral* *abstract base class*. In addition, it provides a few more methods:

`int.`**`bit_length`**`()`

Return the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros:

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

More precisely, if `x` is nonzero, then `x.bit_length()` is the unique positive integer `k` such that `2**(k-1) <= abs(x) < 2**k`. Equivalently, when `abs(x)` is small enough to have a correctly rounded logarithm, then `k = 1 + int(log(abs(x), 2))`. If `x` is zero, then `x.bit_length()` returns `0`.

Equivalent to:

```
def bit_length(self):
    s = bin(self)       # binary representation:  bin(-37) --> '-0b100101'
    s = s.lstrip('-0b') # remove leading zeros and minus sign
    return len(s)       # len('100101') --> 6
```

Added in version 3.1.

`int.`**`bit_count`**`()`

Return the number of ones in the binary representation of the absolute value of the integer. This is also known as the population count. Example:

```
>>> n = 19
>>> bin(n)
'0b10011'
>>> n.bit_count()
3
>>> (-n).bit_count()
3
```

Equivalent to:

```
def bit_count(self):
    return bin(self).count("1")
```

Added in version 3.10.

`int.to_bytes`(*length=1*, *byteorder='big'*, ***, *signed=False*)

Return an array of bytes representing an integer.

```
>>> (1024).to_bytes(2, byteorder='big')
b'\x04\x00'
>>> (1024).to_bytes(10, byteorder='big')
b'\x00\x00\x00\x00\x00\x00\x00\x00\x04\x00'
>>> (-1024).to_bytes(10, byteorder='big', signed=True)
b'\xff\xff\xff\xff\xff\xff\xff\xff\xfc\x00'
>>> x = 1000
>>> x.to_bytes((x.bit_length() + 7) // 8, byteorder='little')
b'\xe8\x03'
```

The integer is represented using *length* bytes, and defaults to 1. An *OverflowError* is raised if the integer is not representable with the given number of bytes.

The *byteorder* argument determines the byte order used to represent the integer, and defaults to `"big"`. If *byteorder* is `"big"`, the most significant byte is at the beginning of the byte array. If *byteorder* is `"little"`, the most significant byte is at the end of the byte array.

The *signed* argument determines whether two's complement is used to represent the integer. If *signed* is `False` and a negative integer is given, an *OverflowError* is raised. The default value for *signed* is `False`.

The default values can be used to conveniently turn an integer into a single byte object:

```
>>> (65).to_bytes()
b'A'
```

However, when using the default arguments, don't try to convert a value greater than 255 or you'll get an *OverflowError*.

Equivalent to:

```
def to_bytes(n, length=1, byteorder='big', signed=False):
    if byteorder == 'little':
        order = range(length)
    elif byteorder == 'big':
        order = reversed(range(length))
    else:
        raise ValueError("byteorder must be either 'little' or 'big'")

    return bytes((n >> i*8) & 0xff for i in order)
```

Added in version 3.2.

Changed in version 3.11: Added default argument values for `length` and `byteorder`.

classmethod int.**from_bytes**(*bytes*, *byteorder='big'*, ***, *signed=False*)

Return the integer represented by the given array of bytes.

```
>>> int.from_bytes(b'\x00\x10', byteorder='big')
16
>>> int.from_bytes(b'\x00\x10', byteorder='little')
4096
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=True)
-1024
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=False)
64512
>>> int.from_bytes([255, 0, 0], byteorder='big')
16711680
```

The argument *bytes* must either be a *bytes-like object* or an iterable producing bytes.

The *byteorder* argument determines the byte order used to represent the integer, and defaults to `"big"`. If *byteorder* is `"big"`, the most significant byte is at the beginning of the byte array. If *byteorder* is `"little"`, the most significant byte is at the end of the byte array. To request the native byte order of the host system, use *`sys.byteorder`* as the byte order value.

The *signed* argument indicates whether two's complement is used to represent the integer.

Equivalent to:

```
def from_bytes(bytes, byteorder='big', signed=False):
    if byteorder == 'little':
        little_ordered = list(bytes)
    elif byteorder == 'big':
        little_ordered = list(reversed(bytes))
    else:
        raise ValueError("byteorder must be either 'little' or 'big'")

    n = sum(b << i*8 for i, b in enumerate(little_ordered))
    if signed and little_ordered and (little_ordered[-1] & 0x80):
        n -= 1 << 8*len(little_ordered)

    return n
```

Added in version 3.2.

Changed in version 3.11: Added default argument value for `byteorder`.

int.**as_integer_ratio**()

Return a pair of integers whose ratio is equal to the original integer and has a positive denominator. The integer ratio of integers (whole numbers) is always the integer as the numerator and `1` as the denominator.

Added in version 3.8.

int.**is_integer**()

Returns `True`. Exists for duck type compatibility with *`float.is_integer()`*.

Added in version 3.12.

4.4.3 Additional Methods on Float

The float type implements the *`numbers.Real`* *abstract base class*. float also has the following additional methods.

float.**as_integer_ratio**()

Return a pair of integers whose ratio is exactly equal to the original float. The ratio is in lowest terms and has a positive denominator. Raises *`OverflowError`* on infinities and a *`ValueError`* on NaNs.

float.**is_integer**()

Return `True` if the float instance is finite with integral value, and `False` otherwise:

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

Two methods support conversion to and from hexadecimal strings. Since Python's floats are stored internally as binary numbers, converting a float to or from a *decimal* string usually involves a small rounding error. In contrast, hexadecimal strings allow exact representation and specification of floating-point numbers. This can be useful when debugging, and in numerical work.

float.**hex**()

Return a representation of a floating-point number as a hexadecimal string. For finite floating-point numbers, this representation will always include a leading `0x` and a trailing `p` and exponent.

classmethod float.**fromhex**(*s*)

Class method to return the float represented by a hexadecimal string *s*. The string *s* may have leading and trailing whitespace.

Note that *float.hex()* is an instance method, while *float.fromhex()* is a class method.

A hexadecimal string takes the form:

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

where the optional `sign` may by either `+` or `-`, `integer` and `fraction` are strings of hexadecimal digits, and `exponent` is a decimal integer with an optional leading sign. Case is not significant, and there must be at least one hexadecimal digit in either the integer or the fraction. This syntax is similar to the syntax specified in section 6.4.4.2 of the C99 standard, and also to the syntax used in Java 1.5 onwards. In particular, the output of *float.hex()* is usable as a hexadecimal floating-point literal in C or Java code, and hexadecimal strings produced by C's `%a` format character or Java's `Double.toHexString` are accepted by *float.fromhex()*.

Note that the exponent is written in decimal rather than hexadecimal, and that it gives the power of 2 by which to multiply the coefficient. For example, the hexadecimal string `0x3.a7p10` represents the floating-point number `(3 + 10./16 + 7./16**2) * 2.0**10`, or `3740.0`:

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

Applying the reverse conversion to `3740.0` gives a different hexadecimal string representing the same number:

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

4.4.4 Hashing of numeric types

For numbers `x` and `y`, possibly of different types, it's a requirement that `hash(x) == hash(y)` whenever `x == y` (see the `__hash__()` method documentation for more details). For ease of implementation and efficiency across a variety of numeric types (including *int*, *float*, *decimal.Decimal* and *fractions.Fraction*) Python's hash for numeric types is based on a single mathematical function that's defined for any rational number, and hence applies to all instances of *int* and *fractions.Fraction*, and all finite instances of *float* and *decimal.Decimal*. Essentially, this function is given by reduction modulo `P` for a fixed prime `P`. The value of `P` is made available to Python as the *modulus* attribute of *sys.hash_info*.

CPython implementation detail: Currently, the prime used is `P = 2**31 - 1` on machines with 32-bit C longs and `P = 2**61 - 1` on machines with 64-bit C longs.

Here are the rules in detail:

- If `x = m / n` is a nonnegative rational number and `n` is not divisible by `P`, define `hash(x)` as `m * invmod(n, P) % P`, where `invmod(n, P)` gives the inverse of `n` modulo `P`.
- If `x = m / n` is a nonnegative rational number and `n` is divisible by `P` (but `m` is not) then `n` has no inverse modulo `P` and the rule above doesn't apply; in this case define `hash(x)` to be the constant value `sys.hash_info.inf`.
- If `x = m / n` is a negative rational number define `hash(x)` as `-hash(-x)`. If the resulting hash is `-1`, replace it with `-2`.
- The particular values `sys.hash_info.inf` and `-sys.hash_info.inf` are used as hash values for positive infinity or negative infinity (respectively).
- For a *complex* number `z`, the hash values of the real and imaginary parts are combined by computing `hash(z.real) + sys.hash_info.imag * hash(z.imag)`, reduced modulo `2**sys.hash_info.width` so that it lies in `range(-2**(sys.hash_info.width - 1), 2**(sys.hash_info.width - 1))`. Again, if the result is `-1`, it's replaced with `-2`.

To clarify the above rules, here's some example Python code, equivalent to the built-in hash, for computing the hash of a rational number, *float*, or *complex*:

```
import sys, math

def hash_fraction(m, n):
    """Compute the hash of a rational number m / n.

    Assumes m and n are integers, with n positive.
    Equivalent to hash(fractions.Fraction(m, n)).

    """
    P = sys.hash_info.modulus
    # Remove common factors of P.  (Unnecessary if m and n already coprime.)
    while m % P == n % P == 0:
        m, n = m // P, n // P

    if n % P == 0:
        hash_value = sys.hash_info.inf
    else:
        # Fermat's Little Theorem: pow(n, P-1, P) is 1, so
        # pow(n, P-2, P) gives the inverse of n modulo P.
        hash_value = (abs(m) % P) * pow(n, P - 2, P) % P
    if m < 0:
        hash_value = -hash_value
    if hash_value == -1:
        hash_value = -2
    return hash_value

def hash_float(x):
    """Compute the hash of a float x."""

    if math.isnan(x):
        return object.__hash__(x)
    elif math.isinf(x):
        return sys.hash_info.inf if x > 0 else -sys.hash_info.inf
    else:
        return hash_fraction(*x.as_integer_ratio())

def hash_complex(z):
    """Compute the hash of a complex number z."""

    hash_value = hash_float(z.real) + sys.hash_info.imag * hash_float(z.imag)
```

(continues on next page)

(continued from previous page)

```
    # do a signed reduction modulo 2**sys.hash_info.width
    M = 2**(sys.hash_info.width - 1)
    hash_value = (hash_value & (M - 1)) - (hash_value & M)
    if hash_value == -1:
        hash_value = -2
    return hash_value
```

4.5 Boolean Type - `bool`

Booleans represent truth values. The *bool* type has exactly two constant instances: `True` and `False`.

The built-in function *bool()* converts any value to a boolean, if the value can be interpreted as a truth value (see section *Truth Value Testing* above).

For logical operations, use the *boolean operators* `and`, `or` and `not`. When applying the bitwise operators `&`, `|`, `^` to two booleans, they return a bool equivalent to the logical operations "and", "or", "xor". However, the logical operators `and`, `or` and `!=` should be preferred over `&`, `|` and `^`.

Deprecated since version 3.12: The use of the bitwise inversion operator `~` is deprecated and will raise an error in Python 3.16.

bool is a subclass of *int* (see *Numeric Types — int, float, complex*). In many numeric contexts, `False` and `True` behave like the integers 0 and 1, respectively. However, relying on this is discouraged; explicitly convert using *int()* instead.

4.6 Iterator Types

Python supports a concept of iteration over containers. This is implemented using two distinct methods; these are used to allow user-defined classes to support iteration. Sequences, described below in more detail, always support the iteration methods.

One method needs to be defined for container objects to provide *iterable* support:

`container.__iter__()`

> Return an *iterator* object. The object is required to support the iterator protocol described below. If a container supports different types of iteration, additional methods can be provided to specifically request iterators for those iteration types. (An example of an object supporting multiple forms of iteration would be a tree structure which supports both breadth-first and depth-first traversal.) This method corresponds to the `tp_iter` slot of the type structure for Python objects in the Python/C API.

The iterator objects themselves are required to support the following two methods, which together form the *iterator protocol*:

`iterator.__iter__()`

> Return the *iterator* object itself. This is required to allow both containers and iterators to be used with the `for` and `in` statements. This method corresponds to the `tp_iter` slot of the type structure for Python objects in the Python/C API.

`iterator.__next__()`

> Return the next item from the *iterator*. If there are no further items, raise the *StopIteration* exception. This method corresponds to the `tp_iternext` slot of the type structure for Python objects in the Python/C API.

Python defines several iterator objects to support iteration over general and specific sequence types, dictionaries, and other more specialized forms. The specific types are not important beyond their implementation of the iterator protocol.

Once an iterator's *__next__()* method raises *StopIteration*, it must continue to do so on subsequent calls. Implementations that do not obey this property are deemed broken.

4.6.1 Generator Types

Python's *generator*s provide a convenient way to implement the iterator protocol. If a container object's `__iter__()` method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and `__next__()` methods. More information about generators can be found in the documentation for the yield expression.

4.7 Sequence Types — `list`, `tuple`, `range`

There are three basic sequence types: lists, tuples, and range objects. Additional sequence types tailored for processing of *binary data* and *text strings* are described in dedicated sections.

4.7.1 Common Sequence Operations

The operations in the following table are supported by most sequence types, both mutable and immutable. The `collections.abc.Sequence` ABC is provided to make it easier to correctly implement these operations on custom sequence types.

This table lists the sequence operations sorted in ascending priority. In the table, *s* and *t* are sequences of the same type, *n*, *i*, *j* and *k* are integers and *x* is an arbitrary object that meets any type and value restrictions imposed by *s*.

The `in` and `not in` operations have the same priorities as the comparison operations. The `+` (concatenation) and `*` (repetition) operations have the same priority as the corresponding numeric operations.[3]

Operation	Result	Notes
`x in s`	`True` if an item of *s* is equal to *x*, else `False`	(1)
`x not in s`	`False` if an item of *s* is equal to *x*, else `True`	(1)
`s + t`	the concatenation of *s* and *t*	(6)(7)
`s * n` or `n * s`	equivalent to adding *s* to itself *n* times	(2)(7)
`s[i]`	*i*th item of *s*, origin 0	(3)
`s[i:j]`	slice of *s* from *i* to *j*	(3)(4)
`s[i:j:k]`	slice of *s* from *i* to *j* with step *k*	(3)(5)
`len(s)`	length of *s*	
`min(s)`	smallest item of *s*	
`max(s)`	largest item of *s*	
`s.index(x[, i[, j]])`	index of the first occurrence of *x* in *s* (at or after index *i* and before index *j*)	(8)
`s.count(x)`	total number of occurrences of *x* in *s*	

Sequences of the same type also support comparisons. In particular, tuples and lists are compared lexicographically by comparing corresponding elements. This means that to compare equal, every element must compare equal and the two sequences must be of the same type and have the same length. (For full details see comparisons in the language reference.)

Forward and reversed iterators over mutable sequences access values using an index. That index will continue to march forward (or backward) even if the underlying sequence is mutated. The iterator terminates only when an `IndexError` or a `StopIteration` is encountered (or when the index drops below zero).

Notes:

(1) While the `in` and `not in` operations are used only for simple containment testing in the general case, some specialised sequences (such as `str`, `bytes` and `bytearray`) also use them for subsequence testing:

```
>>> "gg" in "eggs"
True
```

[3] They must have since the parser can't tell the type of the operands.

(2) Values of *n* less than `0` are treated as `0` (which yields an empty sequence of the same type as *s*). Note that items in the sequence *s* are not copied; they are referenced multiple times. This often haunts new Python programmers; consider:

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

What has happened is that `[[]]` is a one-element list containing an empty list, so all three elements of `[[]] * 3` are references to this single empty list. Modifying any of the elements of `lists` modifies this single list. You can create a list of different lists this way:

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

Further explanation is available in the FAQ entry faq-multidimensional-list.

(3) If *i* or *j* is negative, the index is relative to the end of sequence *s*: `len(s) + i` or `len(s) + j` is substituted. But note that `-0` is still `0`.

(4) The slice of *s* from *i* to *j* is defined as the sequence of items with index *k* such that `i <= k < j`. If *i* or *j* is greater than `len(s)`, use `len(s)`. If *i* is omitted or `None`, use `0`. If *j* is omitted or `None`, use `len(s)`. If *i* is greater than or equal to *j*, the slice is empty.

(5) The slice of *s* from *i* to *j* with step *k* is defined as the sequence of items with index `x = i + n*k` such that `0 <= n < (j-i)/k`. In other words, the indices are `i`, `i+k`, `i+2*k`, `i+3*k` and so on, stopping when *j* is reached (but never including *j*). When *k* is positive, *i* and *j* are reduced to `len(s)` if they are greater. When *k* is negative, *i* and *j* are reduced to `len(s) - 1` if they are greater. If *i* or *j* are omitted or `None`, they become "end" values (which end depends on the sign of *k*). Note, *k* cannot be zero. If *k* is `None`, it is treated like `1`.

(6) Concatenating immutable sequences always results in a new object. This means that building up a sequence by repeated concatenation will have a quadratic runtime cost in the total sequence length. To get a linear runtime cost, you must switch to one of the alternatives below:

- if concatenating *`str`* objects, you can build a list and use *`str.join()`* at the end or else write to an *`io.StringIO`* instance and retrieve its value when complete
- if concatenating *`bytes`* objects, you can similarly use *`bytes.join()`* or *`io.BytesIO`*, or you can do in-place concatenation with a *`bytearray`* object. *`bytearray`* objects are mutable and have an efficient overallocation mechanism
- if concatenating *`tuple`* objects, extend a *`list`* instead
- for other types, investigate the relevant class documentation

(7) Some sequence types (such as *`range`*) only support item sequences that follow specific patterns, and hence don't support sequence concatenation or repetition.

(8) `index` raises *`ValueError`* when *x* is not found in *s*. Not all implementations support passing the additional arguments *i* and *j*. These arguments allow efficient searching of subsections of the sequence. Passing the extra arguments is roughly equivalent to using `s[i:j].index(x)`, only without copying any data and with the returned index being relative to the start of the sequence rather than the start of the slice.

4.7.2 Immutable Sequence Types

The only operation that immutable sequence types generally implement that is not also implemented by mutable sequence types is support for the *hash()* built-in.

This support allows immutable sequences, such as *tuple* instances, to be used as *dict* keys and stored in *set* and *frozenset* instances.

Attempting to hash an immutable sequence that contains unhashable values will result in *TypeError*.

4.7.3 Mutable Sequence Types

The operations in the following table are defined on mutable sequence types. The *collections.abc.MutableSequence* ABC is provided to make it easier to correctly implement these operations on custom sequence types.

In the table *s* is an instance of a mutable sequence type, *t* is any iterable object and *x* is an arbitrary object that meets any type and value restrictions imposed by *s* (for example, *bytearray* only accepts integers that meet the value restriction `0 <= x <= 255`).

Operation	Result	Notes
`s[i] = x`	item *i* of *s* is replaced by *x*	
`del s[i]`	removes item *i* of *s*	
`s[i:j] = t`	slice of *s* from *i* to *j* is replaced by the contents of the iterable *t*	
`del s[i:j]`	same as `s[i:j] = []`	
`s[i:j:k] = t`	the elements of `s[i:j:k]` are replaced by those of *t*	(1)
`del s[i:j:k]`	removes the elements of `s[i:j:k]` from the list	
`s.append(x)`	appends *x* to the end of the sequence (same as `s[len(s):len(s)] = [x]`)	
`s.clear()`	removes all items from *s* (same as `del s[:]`)	(5)
`s.copy()`	creates a shallow copy of *s* (same as `s[:]`)	(5)
`s.extend(t)` or `s += t`	extends *s* with the contents of *t* (for the most part the same as `s[len(s):len(s)] = t`)	
`s *= n`	updates *s* with its contents repeated *n* times	(6)
`s.insert(i, x)`	inserts *x* into *s* at the index given by *i* (same as `s[i:i] = [x]`)	
`s.pop()` or `s.pop(i)`	retrieves the item at *i* and also removes it from *s*	(2)
`s.remove(x)`	removes the first item from *s* where `s[i]` is equal to *x*	(3)
`s.reverse()`	reverses the items of *s* in place	(4)

Notes:

(1) If *k* is not equal to `1`, *t* must have the same length as the slice it is replacing.

(2) The optional argument *i* defaults to `-1`, so that by default the last item is removed and returned.

(3) `remove()` raises *ValueError* when *x* is not found in *s*.

(4) The `reverse()` method modifies the sequence in place for economy of space when reversing a large sequence. To remind users that it operates by side effect, it does not return the reversed sequence.

(5) `clear()` and `copy()` are included for consistency with the interfaces of mutable containers that don't support slicing operations (such as *dict* and *set*). `copy()` is not part of the *collections.abc.MutableSequence* ABC, but most concrete mutable sequence classes provide it.

Added in version 3.3: `clear()` and `copy()` methods.

(6) The value *n* is an integer, or an object implementing `__index__()`. Zero and negative values of *n* clear the sequence. Items in the sequence are not copied; they are referenced multiple times, as explained for `s * n` under *Common Sequence Operations*.

4.7.4 Lists

Lists are mutable sequences, typically used to store collections of homogeneous items (where the precise degree of similarity will vary by application).

class list([*iterable*])

Lists may be constructed in several ways:

- Using a pair of square brackets to denote the empty list: `[]`
- Using square brackets, separating items with commas: `[a]`, `[a, b, c]`
- Using a list comprehension: `[x for x in iterable]`
- Using the type constructor: `list()` or `list(iterable)`

The constructor builds a list whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a list, a copy is made and returned, similar to `iterable[:]`. For example, `list('abc')` returns `['a', 'b', 'c']` and `list( (1, 2, 3) )` returns `[1, 2, 3]`. If no argument is given, the constructor creates a new empty list, `[]`.

Many other operations also produce lists, including the *sorted()* built-in.

Lists implement all of the *common* and *mutable* sequence operations. Lists also provide the following additional method:

sort(*, *key=None*, *reverse=False*)

This method sorts the list in place, using only < comparisons between items. Exceptions are not suppressed - if any comparison operations fail, the entire sort operation will fail (and the list will likely be left in a partially modified state).

sort() accepts two arguments that can only be passed by keyword (*keyword-only arguments*):

key specifies a function of one argument that is used to extract a comparison key from each list element (for example, `key=str.lower`). The key corresponding to each item in the list is calculated once and then used for the entire sorting process. The default value of `None` means that list items are sorted directly without calculating a separate key value.

The *functools.cmp_to_key()* utility is available to convert a 2.x style *cmp* function to a *key* function.

reverse is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

This method modifies the sequence in place for economy of space when sorting a large sequence. To remind users that it operates by side effect, it does not return the sorted sequence (use *sorted()* to explicitly request a new sorted list instance).

The *sort()* method is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

For sorting examples and a brief sorting tutorial, see sortinghowto.

CPython implementation detail: While a list is being sorted, the effect of attempting to mutate, or even inspect, the list is undefined. The C implementation of Python makes the list appear empty for the duration, and raises *ValueError* if it can detect that the list has been mutated during a sort.

4.7.5 Tuples

Tuples are immutable sequences, typically used to store collections of heterogeneous data (such as the 2-tuples produced by the *enumerate()* built-in). Tuples are also used for cases where an immutable sequence of homogeneous data is needed (such as allowing storage in a *set* or *dict* instance).

class tuple([*iterable*])

Tuples may be constructed in a number of ways:

- Using a pair of parentheses to denote the empty tuple: `()`
- Using a trailing comma for a singleton tuple: `a,` or `(a,)`
- Separating items with commas: `a, b, c` or `(a, b, c)`
- Using the *tuple()* built-in: `tuple()` or `tuple(iterable)`

The constructor builds a tuple whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a tuple, it is returned unchanged. For example, `tuple('abc')` returns `('a', 'b', 'c')` and `tuple( [1, 2, 3] )` returns `(1, 2, 3)`. If no argument is given, the constructor creates a new empty tuple, `()`.

Note that it is actually the comma which makes a tuple, not the parentheses. The parentheses are optional, except in the empty tuple case, or when they are needed to avoid syntactic ambiguity. For example, `f(a, b, c)` is a function call with three arguments, while `f((a, b, c))` is a function call with a 3-tuple as the sole argument.

Tuples implement all of the *common* sequence operations.

For heterogeneous collections of data where access by name is clearer than access by index, *collections.namedtuple()* may be a more appropriate choice than a simple tuple object.

4.7.6 Ranges

The *range* type represents an immutable sequence of numbers and is commonly used for looping a specific number of times in `for` loops.

class range(*stop*)

class range(*start*, *stop*[, *step*])

The arguments to the range constructor must be integers (either built-in *int* or any object that implements the `__index__()` special method). If the *step* argument is omitted, it defaults to `1`. If the *start* argument is omitted, it defaults to `0`. If *step* is zero, *ValueError* is raised.

For a positive *step*, the contents of a range `r` are determined by the formula `r[i] = start + step*i` where `i >= 0` and `r[i] < stop`.

For a negative *step*, the contents of the range are still determined by the formula `r[i] = start + step*i`, but the constraints are `i >= 0` and `r[i] > stop`.

A range object will be empty if `r[0]` does not meet the value constraint. Ranges do support negative indices, but these are interpreted as indexing from the end of the sequence determined by the positive indices.

Ranges containing absolute values larger than *sys.maxsize* are permitted but some features (such as *len()*) may raise *OverflowError*.

Range examples:

```
>>> list(range(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> list(range(0, 30, 5))
[0, 5, 10, 15, 20, 25]
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
>>> list(range(0, -10, -1))
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> list(range(0))
[]
>>> list(range(1, 0))
[]
```

Ranges implement all of the *common* sequence operations except concatenation and repetition (due to the fact that range objects can only represent sequences that follow a strict pattern and repetition and concatenation will usually violate that pattern).

start

The value of the *start* parameter (or `0` if the parameter was not supplied)

stop

The value of the *stop* parameter

step

The value of the *step* parameter (or `1` if the parameter was not supplied)

The advantage of the *range* type over a regular *list* or *tuple* is that a *range* object will always take the same (small) amount of memory, no matter the size of the range it represents (as it only stores the `start`, `stop` and `step` values, calculating individual items and subranges as needed).

Range objects implement the *collections.abc.Sequence* ABC, and provide features such as containment tests, element index lookup, slicing and support for negative indices (see *Sequence Types — list, tuple, range*):

```
>>> r = range(0, 20, 2)
>>> r
range(0, 20, 2)
>>> 11 in r
False
>>> 10 in r
True
>>> r.index(10)
5
>>> r[5]
10
>>> r[:5]
range(0, 10, 2)
>>> r[-1]
18
```

Testing range objects for equality with `==` and `!=` compares them as sequences. That is, two range objects are considered equal if they represent the same sequence of values. (Note that two range objects that compare equal might have different *start*, *stop* and *step* attributes, for example `range(0) == range(2, 1, 3)` or `range(0, 3, 2) == range(0, 4, 2)`.)

Changed in version 3.2: Implement the Sequence ABC. Support slicing and negative indices. Test *int* objects for membership in constant time instead of iterating through all items.

Changed in version 3.3: Define '==' and '!=' to compare range objects based on the sequence of values they define (instead of comparing based on object identity).

Added the *start*, *stop* and *step* attributes.

See also

- The linspace recipe shows how to implement a lazy version of range suitable for floating-point applications.

4.8 Text Sequence Type — `str`

Textual data in Python is handled with *str* objects, or *strings*. Strings are immutable *sequences* of Unicode code points. String literals are written in a variety of ways:

- Single quotes: `'allows embedded "double" quotes'`

- Double quotes: `"allows embedded 'single' quotes"`
- Triple quoted: `'''Three single quotes'''`, `"""Three double quotes"""`

Triple quoted strings may span multiple lines - all associated whitespace will be included in the string literal.

String literals that are part of a single expression and have only whitespace between them will be implicitly converted to a single string literal. That is, `("spam " "eggs") == "spam eggs"`.

See strings for more about the various forms of string literal, including supported escape sequences, and the `r` ("raw") prefix that disables most escape sequence processing.

Strings may also be created from other objects using the *`str`* constructor.

Since there is no separate "character" type, indexing a string produces strings of length 1. That is, for a non-empty string *s*, `s[0] == s[0:1]`.

There is also no mutable string type, but *`str.join()`* or *`io.StringIO`* can be used to efficiently construct strings from multiple fragments.

Changed in version 3.3: For backwards compatibility with the Python 2 series, the `u` prefix is once again permitted on string literals. It has no effect on the meaning of string literals and cannot be combined with the `r` prefix.

class str(*object=''*)

class str(*object=b''*, *encoding='utf-8'*, *errors='strict'*)

Return a *string* version of *object*. If *object* is not provided, returns the empty string. Otherwise, the behavior of `str()` depends on whether *encoding* or *errors* is given, as follows.

If neither *encoding* nor *errors* is given, `str(object)` returns `type(object).__str__(object)`, which is the "informal" or nicely printable string representation of *object*. For string objects, this is the string itself. If *object* does not have a `__str__()` method, then *`str()`* falls back to returning *`repr(object)`*.

If at least one of *encoding* or *errors* is given, *object* should be a *bytes-like object* (e.g. *`bytes`* or *`bytearray`*). In this case, if *object* is a *`bytes`* (or *`bytearray`*) object, then `str(bytes, encoding, errors)` is equivalent to *`bytes.decode(encoding, errors)`*. Otherwise, the bytes object underlying the buffer object is obtained before calling *`bytes.decode()`*. See *Binary Sequence Types — bytes, bytearray, memoryview* and bufferobjects for information on buffer objects.

Passing a *`bytes`* object to *`str()`* without the *encoding* or *errors* arguments falls under the first case of returning the informal string representation (see also the `-b` command-line option to Python). For example:

```
>>> str(b'Zoot!')
"b'Zoot!'"
```

For more information on the `str` class and its methods, see *Text Sequence Type — str* and the *String Methods* section below. To output formatted strings, see the f-strings and *Format String Syntax* sections. In addition, see the *Text Processing Services* section.

4.8.1 String Methods

Strings implement all of the *common* sequence operations, along with the additional methods described below.

Strings also support two styles of string formatting, one providing a large degree of flexibility and customization (see *`str.format()`*, *Format String Syntax* and *Custom String Formatting*) and the other based on C `printf` style formatting that handles a narrower range of types and is slightly harder to use correctly, but is often faster for the cases it can handle (*printf-style String Formatting*).

The *Text Processing Services* section of the standard library covers a number of other modules that provide various text related utilities (including regular expression support in the *`re`* module).

`str.`**capitalize**`()`

Return a copy of the string with its first character capitalized and the rest lowercased.

Changed in version 3.8: The first character is now put into titlecase rather than uppercase. This means that characters like digraphs will only have their first letter capitalized, instead of the full character.

str.**casefold**()

Return a casefolded copy of the string. Casefolded strings may be used for caseless matching.

Casefolding is similar to lowercasing but more aggressive because it is intended to remove all case distinctions in a string. For example, the German lowercase letter `'ß'` is equivalent to `"ss"`. Since it is already lowercase, *lower()* would do nothing to `'ß'`; *casefold()* converts it to `"ss"`.

The casefolding algorithm is described in section 3.13 'Default Case Folding' of the Unicode Standard.

Added in version 3.3.

str.**center**(*width*[, *fillchar*])

Return centered in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`. For example:

```
>>> 'Python'.center(10)
'  Python  '
>>> 'Python'.center(10, '-')
'--Python--'
>>> 'Python'.center(4)
'Python'
```

str.**count**(*sub*[, *start*[, *end*]])

Return the number of non-overlapping occurrences of substring *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

If *sub* is empty, returns the number of empty strings between characters which is the length of the string plus one. For example:

```
>>> 'spam, spam, spam'.count('spam')
3
>>> 'spam, spam, spam'.count('spam', 5)
2
>>> 'spam, spam, spam'.count('spam', 5, 10)
1
>>> 'spam, spam, spam'.count('eggs')
0
>>> 'spam, spam, spam'.count('')
17
```

str.**encode**(*encoding='utf-8'*, *errors='strict'*)

Return the string encoded to *bytes*.

encoding defaults to `'utf-8'`; see *Standard Encodings* for possible values.

errors controls how encoding errors are handled. If `'strict'` (the default), a *UnicodeError* exception is raised. Other possible values are `'ignore'`, `'replace'`, `'xmlcharrefreplace'`, `'backslashreplace'` and any other name registered via *codecs.register_error()*. See *Error Handlers* for details.

For performance reasons, the value of *errors* is not checked for validity unless an encoding error actually occurs, *Python Development Mode* is enabled or a debug build is used.

Changed in version 3.1: Added support for keyword arguments.

Changed in version 3.9: The value of the *errors* argument is now checked in *Python Development Mode* and in debug mode.

str.**endswith**(*suffix*[, *start*[, *end*]])

Return `True` if the string ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

str.**expandtabs**(*tabsize=8*)

Return a copy of the string where all tab characters are replaced by one or more spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* characters (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the string, the current column is set to zero and the string is examined character by character. If the character is a tab (`\t`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the character is a newline (`\n`) or return (`\r`), it is copied and the current column is reset to zero. Any other character is copied unchanged and the current column is incremented by one regardless of how the character is represented when printed.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012     0123    01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123    01234'
```

str.**find**(*sub*[, *start*[, *end*]])

Return the lowest index in the string where substring *sub* is found within the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

Note

The *find()* method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> 'Py' in 'Python'
True
```

str.**format**(**args*, ***kwargs*)

Perform a string formatting operation. The string on which this method is called can contain literal text or replacement fields delimited by braces `{}`. Each replacement field contains either the numeric index of a positional argument, or the name of a keyword argument. Returns a copy of the string where each replacement field is replaced with the string value of the corresponding argument.

```
>>> "The sum of 1 + 2 is {0}".format(1+2)
'The sum of 1 + 2 is 3'
```

See *Format String Syntax* for a description of the various formatting options that can be specified in format strings.

Note

When formatting a number (*int*, *float*, *complex*, *decimal.Decimal* and subclasses) with the `n` type (ex: `'{:n}'.format(1234)`), the function temporarily sets the `LC_CTYPE` locale to the `LC_NUMERIC` locale to decode `decimal_point` and `thousands_sep` fields of `localeconv()` if they are non-ASCII or longer than 1 byte, and the `LC_NUMERIC` locale is different than the `LC_CTYPE` locale. This temporary change affects other threads.

Changed in version 3.7: When formatting a number with the `n` type, the function sets temporarily the `LC_CTYPE` locale to the `LC_NUMERIC` locale in some cases.

str.**format_map**(*mapping*, */*)

Similar to `str.format(**mapping)`, except that `mapping` is used directly and not copied to a *dict*. This is useful if for example `mapping` is a dict subclass:

```
>>> class Default(dict):
...     def __missing__(self, key):
```

(continues on next page)

(continued from previous page)

```
...         return key
...
>>> '{name} was born in {country}'.format_map(Default(name='Guido'))
'Guido was born in country'
```

Added in version 3.2.

`str.`**`index`**`(`*sub*`[, `*start*`[, `*end*`]])`

Like *`find()`*, but raise *`ValueError`* when the substring is not found.

`str.`**`isalnum`**`()`

Return `True` if all characters in the string are alphanumeric and there is at least one character, `False` otherwise. A character `c` is alphanumeric if one of the following returns `True`: `c.isalpha()`, `c.isdecimal()`, `c.isdigit()`, or `c.isnumeric()`.

`str.`**`isalpha`**`()`

Return `True` if all characters in the string are alphabetic and there is at least one character, `False` otherwise. Alphabetic characters are those characters defined in the Unicode character database as "Letter", i.e., those with general category property being one of "Lm", "Lt", "Lu", "Ll", or "Lo". Note that this is different from the Alphabetic property defined in the section 4.10 'Letters, Alphabetic, and Ideographic' of the Unicode Standard.

`str.`**`isascii`**`()`

Return `True` if the string is empty or all characters in the string are ASCII, `False` otherwise. ASCII characters have code points in the range U+0000-U+007F.

Added in version 3.7.

`str.`**`isdecimal`**`()`

Return `True` if all characters in the string are decimal characters and there is at least one character, `False` otherwise. Decimal characters are those that can be used to form numbers in base 10, e.g. U+0660, ARABIC-INDIC DIGIT ZERO. Formally a decimal character is a character in the Unicode General Category "Nd".

`str.`**`isdigit`**`()`

Return `True` if all characters in the string are digits and there is at least one character, `False` otherwise. Digits include decimal characters and digits that need special handling, such as the compatibility superscript digits. This covers digits which cannot be used to form numbers in base 10, like the Kharosthi numbers. Formally, a digit is a character that has the property value Numeric_Type=Digit or Numeric_Type=Decimal.

`str.`**`isidentifier`**`()`

Return `True` if the string is a valid identifier according to the language definition, section identifiers.

`keyword.iskeyword()` can be used to test whether string `s` is a reserved identifier, such as `def` and `class`.

Example:

```
>>> from keyword import iskeyword

>>> 'hello'.isidentifier(), iskeyword('hello')
(True, False)
>>> 'def'.isidentifier(), iskeyword('def')
(True, True)
```

`str.`**`islower`**`()`

Return `True` if all cased characters[4] in the string are lowercase and there is at least one cased character, `False` otherwise.

[4] Cased characters are those with general category property being one of "Lu" (Letter, uppercase), "Ll" (Letter, lowercase), or "Lt" (Letter, titlecase).

str.**isnumeric**()

Return `True` if all characters in the string are numeric characters, and there is at least one character, `False` otherwise. Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH. Formally, numeric characters are those with the property value Numeric_Type=Digit, Numeric_Type=Decimal or Numeric_Type=Numeric.

str.**isprintable**()

Return `True` if all characters in the string are printable, `False` if it contains at least one non-printable character.

Here "printable" means the character is suitable for *repr()* to use in its output; "non-printable" means that *repr()* on built-in types will hex-escape the character. It has no bearing on the handling of strings written to *sys.stdout* or *sys.stderr*.

The printable characters are those which in the Unicode character database (see *unicodedata*) have a general category in group Letter, Mark, Number, Punctuation, or Symbol (L, M, N, P, or S); plus the ASCII space 0x20. Nonprintable characters are those in group Separator or Other (Z or C), except the ASCII space.

str.**isspace**()

Return `True` if there are only whitespace characters in the string and there is at least one character, `False` otherwise.

A character is *whitespace* if in the Unicode character database (see *unicodedata*), either its general category is `Zs` ("Separator, space"), or its bidirectional class is one of `WS`, `B`, or `S`.

str.**istitle**()

Return `True` if the string is a titlecased string and there is at least one character, for example uppercase characters may only follow uncased characters and lowercase characters only cased ones. Return `False` otherwise.

str.**isupper**()

Return `True` if all cased characters[Page 55, 4] in the string are uppercase and there is at least one cased character, `False` otherwise.

```
>>> 'BANANA'.isupper()
True
>>> 'banana'.isupper()
False
>>> 'baNana'.isupper()
False
>>> ' '.isupper()
False
```

str.**join**(*iterable*)

Return a string which is the concatenation of the strings in *iterable*. A *TypeError* will be raised if there are any non-string values in *iterable*, including *bytes* objects. The separator between elements is the string providing this method.

str.**ljust**(*width*[, *fillchar*])

Return the string left justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

str.**lower**()

Return a copy of the string with all the cased characters[Page 55, 4] converted to lowercase.

The lowercasing algorithm used is described in section 3.13 'Default Case Folding' of the Unicode Standard.

str.**lstrip**([*chars*])

Return a copy of the string with leading characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.lstrip()
'spacious   '
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

See *str.removeprefix()* for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> 'Arthur: three!'.lstrip('Arthur: ')
'ee!'
>>> 'Arthur: three!'.removeprefix('Arthur: ')
'three!'
```

static str.**maketrans**(*x*[, *y*[, *z*]])

This static method returns a translation table usable for *str.translate()*.

If there is only one argument, it must be a dictionary mapping Unicode ordinals (integers) or characters (strings of length 1) to Unicode ordinals, strings (of arbitrary lengths) or `None`. Character keys will then be converted to ordinals.

If there are two arguments, they must be strings of equal length, and in the resulting dictionary, each character in x will be mapped to the character at the same position in y. If there is a third argument, it must be a string, whose characters will be mapped to `None` in the result.

str.**partition**(*sep*)

Split the string at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing the string itself, followed by two empty strings.

str.**removeprefix**(*prefix*, /)

If the string starts with the *prefix* string, return `string[len(prefix):]`. Otherwise, return a copy of the original string:

```
>>> 'TestHook'.removeprefix('Test')
'Hook'
>>> 'BaseTestCase'.removeprefix('Test')
'BaseTestCase'
```

Added in version 3.9.

str.**removesuffix**(*suffix*, /)

If the string ends with the *suffix* string and that *suffix* is not empty, return `string[:-len(suffix)]`. Otherwise, return a copy of the original string:

```
>>> 'MiscTests'.removesuffix('Tests')
'Misc'
>>> 'TmpDirMixin'.removesuffix('Tests')
'TmpDirMixin'
```

Added in version 3.9.

str.**replace**(*old*, *new*, *count=-1*)

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If *count* is given, only the first *count* occurrences are replaced. If *count* is not specified or `-1`, then all occurrences are replaced.

Changed in version 3.13: *count* is now supported as a keyword argument.

str.**rfind**(*sub*[, *start*[, *end*]])

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

str.**rindex**(*sub*[, *start*[, *end*]])

Like *rfind()* but raises *ValueError* when the substring *sub* is not found.

str.**rjust**(*width*[, *fillchar*])

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

str.**rpartition**(*sep*)

Split the string at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty strings, followed by the string itself.

str.**rsplit**(*sep=None*, *maxsplit=-1*)

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any whitespace string is a separator. Except for splitting from the right, *rsplit()* behaves like *split()* which is described in detail below.

str.**rstrip**([*chars*])

Return a copy of the string with trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

See *str.removesuffix()* for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> 'Monty Python'.rstrip(' Python')
'M'
>>> 'Monty Python'.removesuffix(' Python')
'Monty'
```

str.**split**(*sep=None*, *maxsplit=-1*)

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done (thus, the list will have at most `maxsplit+1` elements). If *maxsplit* is not specified or `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty strings (for example, `'1,,2'.split(',')` returns `['1', '', '2']`). The *sep* argument may consist of multiple characters as a single delimiter (to split with multiple delimiters, use *re.split()*). Splitting an empty string with a specified separator returns `['']`.

For example:

```
>>> '1,2,3'.split(',')
['1', '2', '3']
>>> '1,2,3'.split(',', maxsplit=1)
['1', '2,3']
>>> '1,2,,3,'.split(',')
['1', '2', '', '3', '']
>>> '1<>2<>3<4'.split('<>')
['1', '2', '3<4']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the string has leading or trailing whitespace. Consequently, splitting an empty string or a string consisting of just whitespace with a `None` separator returns `[]`.

For example:

```
>>> '1 2 3'.split()
['1', '2', '3']
>>> '1 2 3'.split(maxsplit=1)
['1', '2 3']
>>> '   1   2   3   '.split()
['1', '2', '3']
```

If *sep* is not specified or is `None` and *maxsplit* is `0`, only leading runs of consecutive whitespace are considered.

For example:

```
>>> "".split(None, 0)
[]
>>> "   ".split(None, 0)
[]
>>> "   foo   ".split(maxsplit=0)
['foo   ']
```

`str.`**`splitlines`**`(`*keepends=False*`)`

Return a list of the lines in the string, breaking at line boundaries. Line breaks are not included in the resulting list unless *keepends* is given and true.

This method splits on the following line boundaries. In particular, the boundaries are a superset of *universal newlines*.

Representation	Description
`\n`	Line Feed
`\r`	Carriage Return
`\r\n`	Carriage Return + Line Feed
`\v` or `\x0b`	Line Tabulation
`\f` or `\x0c`	Form Feed
`\x1c`	File Separator
`\x1d`	Group Separator
`\x1e`	Record Separator
`\x85`	Next Line (C1 Control Code)
`\u2028`	Line Separator
`\u2029`	Paragraph Separator

Changed in version 3.2: `\v` and `\f` added to list of line boundaries.

For example:

```
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

Unlike *`split()`* when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

For comparison, `split('\n')` gives:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

str.**startswith**(*prefix*[, *start*[, *end*]])

Return `True` if string starts with the *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test string beginning at that position. With optional *end*, stop comparing string at that position.

str.**strip**([*chars*])

Return a copy of the string with the leading and trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

The outermost leading and trailing *chars* argument values are stripped from the string. Characters are removed from the leading end until reaching a string character that is not contained in the set of characters in *chars*. A similar action takes place on the trailing end. For example:

```
>>> comment_string = '#....... Section 3.2.1 Issue #32 .......'
>>> comment_string.strip('.#! ')
'Section 3.2.1 Issue #32'
```

str.**swapcase**()

Return a copy of the string with uppercase characters converted to lowercase and vice versa. Note that it is not necessarily true that `s.swapcase().swapcase() == s`.

str.**title**()

Return a titlecased version of the string where words start with an uppercase character and the remaining characters are lowercase.

For example:

```
>>> 'Hello world'.title()
'Hello World'
```

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> "they're bill's friends from the UK".title()
"They're Bill'S Friends From The Uk"
```

The *`string.capwords()`* function does not have this problem, as it splits words on spaces only.

Alternatively, a workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+('[A-Za-z]+)?",
...                   lambda mo: mo.group(0).capitalize(),
...                   s)
...
```

(continues on next page)

(continued from previous page)

```
>>> titlecase("they're bill's friends.")
"They're Bill's Friends."
```

`str.`**`translate`**`(`*table*`)`

Return a copy of the string in which each character has been mapped through the given translation table. The table must be an object that implements indexing via `__getitem__()`, typically a *mapping* or *sequence*. When indexed by a Unicode ordinal (an integer), the table object can do any of the following: return a Unicode ordinal or a string, to map the character to one or more other characters; return `None`, to delete the character from the return string; or raise a *`LookupError`* exception, to map the character to itself.

You can use *`str.maketrans()`* to create a translation map from character-to-character mappings in different formats.

See also the *`codecs`* module for a more flexible approach to custom character mappings.

`str.`**`upper`**`()`

Return a copy of the string with all the cased characters[Page 55, 4] converted to uppercase. Note that `s.upper().isupper()` might be `False` if `s` contains uncased characters or if the Unicode category of the resulting character(s) is not "Lu" (Letter, uppercase), but e.g. "Lt" (Letter, titlecase).

The uppercasing algorithm used is described in section 3.13 'Default Case Folding' of the Unicode Standard.

`str.`**`zfill`**`(`*width*`)`

Return a copy of the string left filled with ASCII `'0'` digits to make a string of length *width*. A leading sign prefix (`'+'`/`'-'`) is handled by inserting the padding *after* the sign character rather than before. The original string is returned if *width* is less than or equal to `len(s)`.

For example:

```
>>> "42".zfill(5)
'00042'
>>> "-42".zfill(5)
'-0042'
```

4.8.2 Formatted String Literals (f-strings)

Added in version 3.6.

Changed in version 3.7: The `await` and `async for` can be used in expressions within f-strings.

Changed in version 3.8: Added the debugging operator (=)

Changed in version 3.12: Many restrictions on expressions within f-strings have been removed. Notably, nested strings, comments, and backslashes are now permitted.

An *f-string* (formally a *formatted string literal*) is a string literal that is prefixed with `f` or `F`. This type of string literal allows embedding arbitrary Python expressions within *replacement fields*, which are delimited by curly brackets (`{}`). These expressions are evaluated at runtime, similarly to *`str.format()`*, and are converted into regular *`str`* objects. For example:

```
>>> who = 'nobody'
>>> nationality = 'Spanish'
>>> f'{who.title()} expects the {nationality} Inquisition!'
'Nobody expects the Spanish Inquisition!'
```

It is also possible to use a multi line f-string:

```
>>> f'''This is a string
... on two lines'''
'This is a string\non two lines'
```

A single opening curly bracket, `'{'`, marks a *replacement field* that can contain any Python expression:

```
>>> nationality = 'Spanish'
>>> f'The {nationality} Inquisition!'
'The Spanish Inquisition!'
```

To include a literal `{` or `}`, use a double bracket:

```
>>> x = 42
>>> f'{{x}} is {x}'
'{x} is 42'
```

Functions can also be used, and *format specifiers*:

```
>>> from math import sqrt
>>> f'√2 \N{ALMOST EQUAL TO} {sqrt(2):.5f}'
'√2 ≈ 1.41421'
```

Any non-string expression is converted using *str()*, by default:

```
>>> from fractions import Fraction
>>> f'{Fraction(1, 3)}'
'1/3'
```

To use an explicit conversion, use the `!` (exclamation mark) operator, followed by any of the valid formats, which are:

Conversion	Meaning
`!a`	*ascii()*
`!r`	*repr()*
`!s`	*str()*

For example:

```
>>> from fractions import Fraction
>>> f'{Fraction(1, 3)!s}'
'1/3'
>>> f'{Fraction(1, 3)!r}'
'Fraction(1, 3)'
>>> question = '¿Dónde está el Presidente?'
>>> print(f'{question!a}')
'\xbfD\xf3nde est\xe1 el Presidente?'
```

While debugging it may be helpful to see both the expression and its value, by using the equals sign (=) after the expression. This preserves spaces within the brackets, and can be used with a converter. By default, the debugging operator uses the *repr()* (`!r`) conversion. For example:

```
>>> from fractions import Fraction
>>> calculation = Fraction(1, 3)
>>> f'{calculation=}'
'calculation=Fraction(1, 3)'
>>> f'{calculation = }'
'calculation = Fraction(1, 3)'
>>> f'{calculation = !s}'
'calculation = 1/3'
```

Once the output has been evaluated, it can be formatted using a *format specifier* following a colon (`':'`). After the expression has been evaluated, and possibly converted to a string, the `__format__()` method of the result is called

with the format specifier, or the empty string if no format specifier is given. The formatted result is then used as the final value for the replacement field. For example:

```
>>> from fractions import Fraction
>>> f'{Fraction(1, 7):.6f}'
'0.142857'
>>> f'{Fraction(1, 7):_^+10}'
'___+1/7___'
```

4.8.3 `printf`-style String Formatting

> **Note**
>
> The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). Using the newer formatted string literals, the *`str.format()`* interface, or *template strings* may help avoid these errors. Each of these alternatives provides their own trade-offs and benefits of simplicity, flexibility, and/or extensibility.

String objects have one unique built-in operation: the `%` operator (modulo). This is also known as the string *formatting* or *interpolation* operator. Given `format % values` (where *format* is a string), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to using the `sprintf()` function in the C language. For example:

```
>>> print('%s has %d quote types.' % ('Python', 2))
Python has 2 quote types.
```

If *format* requires a single argument, *values* may be a single non-tuple object.[5] Otherwise, *values* must be a tuple with exactly the number of items specified by the format string, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the string *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print('%(language)s has %(number)03d quote types.' %
...       {'language': "Python", "number": 2})
Python has 002 quote types.
```

In this case no `*` specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

[5] To format only a tuple you should therefore provide a singleton tuple whose only element is the tuple to be formatted.

Flag	Meaning
'#'	The value conversion will use the "alternate form" (where defined below).
'0'	The conversion will be zero padded for numeric values.
'-'	The converted value is left adjusted (overrides the '0' conversion if both are given).
' '	(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
'+'	A sign character ('+' or '-') will precede the conversion (overrides a "space" flag).

A length modifier (h, l, or L) may be present, but is ignored as it is not necessary for Python – so e.g. %ld is identical to %d.

The conversion types are:

Conversion	Meaning	Notes
'd'	Signed integer decimal.	
'i'	Signed integer decimal.	
'o'	Signed octal value.	(1)
'u'	Obsolete type – it is identical to 'd'.	(6)
'x'	Signed hexadecimal (lowercase).	(2)
'X'	Signed hexadecimal (uppercase).	(2)
'e'	Floating-point exponential format (lowercase).	(3)
'E'	Floating-point exponential format (uppercase).	(3)
'f'	Floating-point decimal format.	(3)
'F'	Floating-point decimal format.	(3)
'g'	Floating-point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
'G'	Floating-point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
'c'	Single character (accepts integer or single character string).	
'r'	String (converts any Python object using *repr()*).	(5)
's'	String (converts any Python object using *str()*).	(5)
'a'	String (converts any Python object using *ascii()*).	(5)
'%'	No argument is converted, results in a '%' character in the result.	

Notes:

(1) The alternate form causes a leading octal specifier ('0o') to be inserted before the first digit.

(2) The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.

(3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.

The precision determines the number of digits after the decimal point and defaults to 6.

(4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

(5) If precision is N, the output is truncated to N characters.

(6) See **PEP 237**.

Since Python strings have an explicit length, %s conversions do not assume that '\0' is the end of the string.

Changed in version 3.1: %f conversions for numbers whose absolute value is over 1e50 are no longer replaced by %g conversions.

4.9 Binary Sequence Types — bytes, bytearray, memoryview

The core built-in types for manipulating binary data are *bytes* and *bytearray*. They are supported by *memoryview* which uses the buffer protocol to access the memory of other binary objects without needing to make a copy.

The *array* module supports efficient storage of basic data types like 32-bit integers and IEEE754 double-precision floating values.

4.9.1 Bytes Objects

Bytes objects are immutable sequences of single bytes. Since many major binary protocols are based on the ASCII text encoding, bytes objects offer several methods that are only valid when working with ASCII compatible data and are closely related to string objects in a variety of other ways.

class bytes([*source*[, *encoding*[, *errors*]]])

Firstly, the syntax for bytes literals is largely the same as that for string literals, except that a `b` prefix is added:

- Single quotes: `b'still allows embedded "double" quotes'`
- Double quotes: `b"still allows embedded 'single' quotes"`
- Triple quoted: `b'''3 single quotes'''`, `b"""3 double quotes"""`

Only ASCII characters are permitted in bytes literals (regardless of the declared source code encoding). Any binary values over 127 must be entered into bytes literals using the appropriate escape sequence.

As with string literals, bytes literals may also use a `r` prefix to disable processing of escape sequences. See strings for more about the various forms of bytes literal, including supported escape sequences.

While bytes literals and representations are based on ASCII text, bytes objects actually behave like immutable sequences of integers, with each value in the sequence restricted such that `0 <= x < 256` (attempts to violate this restriction will trigger *ValueError*). This is done deliberately to emphasise that while many binary formats include ASCII based elements and can be usefully manipulated with some text-oriented algorithms, this is not generally the case for arbitrary binary data (blindly applying text processing algorithms to binary data formats that are not ASCII compatible will usually lead to data corruption).

In addition to the literal forms, bytes objects can be created in a number of other ways:

- A zero-filled bytes object of a specified length: `bytes(10)`
- From an iterable of integers: `bytes(range(20))`
- Copying existing binary data via the buffer protocol: `bytes(obj)`

Also see the *bytes* built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytes type has an additional class method to read data in that format:

classmethod fromhex(*string*)

This *bytes* class method returns a bytes object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytes.fromhex('2Ef0 F1f2  ')
b'.\xf0\xf1\xf2'
```

Changed in version 3.7: *bytes.fromhex()* now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytes object into its hexadecimal representation.

hex([*sep*[, *bytes_per_sep*]])

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> b'\xf0\xf1\xf2'.hex()
'f0f1f2'
```

If you want to make the hex string easier to read, you can specify a single character separator *sep* parameter to include in the output. By default, this separator will be included between each byte. A second optional *bytes_per_sep* parameter controls the spacing. Positive values calculate the separator position from the right, negative values from the left.

```
>>> value = b'\xf0\xf1\xf2'
>>> value.hex('-')
'f0-f1-f2'
>>> value.hex('_', 2)
'f0_f1f2'
>>> b'UUDDLRLRAB'.hex(' ', -4)
'55554444 4c524c52 4142'
```

Added in version 3.5.

Changed in version 3.8: *bytes.hex()* now supports optional *sep* and *bytes_per_sep* parameters to insert separators between bytes in the hex output.

Since bytes objects are sequences of integers (akin to a tuple), for a bytes object *b*, `b[0]` will be an integer, while `b[0:1]` will be a bytes object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytes objects uses the literal format (`b'...'`) since it is often more useful than e.g. `bytes([46, 46, 46])`. You can always convert a bytes object into a list of integers using `list(b)`.

4.9.2 Bytearray Objects

bytearray objects are a mutable counterpart to *bytes* objects.

class bytearray([*source*[, *encoding*[, *errors*]]])

There is no dedicated literal syntax for bytearray objects, instead they are always created by calling the constructor:

- Creating an empty instance: `bytearray()`
- Creating a zero-filled instance with a given length: `bytearray(10)`
- From an iterable of integers: `bytearray(range(20))`
- Copying existing binary data via the buffer protocol: `bytearray(b'Hi!')`

As bytearray objects are mutable, they support the *mutable* sequence operations in addition to the common bytes and bytearray operations described in *Bytes and Bytearray Operations*.

Also see the *bytearray* built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytearray type has an additional class method to read data in that format:

classmethod fromhex(*string*)

This *bytearray* class method returns bytearray object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytearray.fromhex('2Ef0 F1f2  ')
bytearray(b'.\xf0\xf1\xf2')
```

Changed in version 3.7: *bytearray.fromhex()* now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytearray object into its hexadecimal representation.

hex([*sep*[, *bytes_per_sep*]])

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> bytearray(b'\xf0\xf1\xf2').hex()
'f0f1f2'
```

Added in version 3.5.

Changed in version 3.8: Similar to *bytes.hex()*, *bytearray.hex()* now supports optional *sep* and *bytes_per_sep* parameters to insert separators between bytes in the hex output.

Since bytearray objects are sequences of integers (akin to a list), for a bytearray object *b*, `b[0]` will be an integer, while `b[0:1]` will be a bytearray object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytearray objects uses the bytes literal format (`bytearray(b'...')`) since it is often more useful than e.g. `bytearray([46, 46, 46])`. You can always convert a bytearray object into a list of integers using `list(b)`.

4.9.3 Bytes and Bytearray Operations

Both bytes and bytearray objects support the *common* sequence operations. They interoperate not just with operands of the same type, but with any *bytes-like object*. Due to this flexibility, they can be freely mixed in operations without causing errors. However, the return type of the result may depend on the order of operands.

Note

The methods on bytes and bytearray objects don't accept strings as their arguments, just as the methods on strings don't accept bytes as their arguments. For example, you have to write:

```
a = "abc"
b = a.replace("a", "f")
```

and:

```
a = b"abc"
b = a.replace(b"a", b"f")
```

Some bytes and bytearray operations assume the use of ASCII compatible binary formats, and hence should be avoided when working with arbitrary binary data. These restrictions are covered below.

Note

Using these ASCII based operations to manipulate binary data that is not stored in an ASCII based format may lead to data corruption.

The following methods on bytes and bytearray objects can be used with arbitrary binary data.

`bytes.`**count**(*sub*[, *start*[, *end*]])

`bytearray.`**count**(*sub*[, *start*[, *end*]])

Return the number of non-overlapping occurrences of subsequence *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

If *sub* is empty, returns the number of empty slices between characters which is the length of the bytes object plus one.

Changed in version 3.3: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.`**removeprefix**(*prefix*, /)

bytearray.**removeprefix**(*prefix*, /)

If the binary data starts with the *prefix* string, return `bytes[len(prefix):]`. Otherwise, return a copy of the original binary data:

```
>>> b'TestHook'.removeprefix(b'Test')
b'Hook'
>>> b'BaseTestCase'.removeprefix(b'Test')
b'BaseTestCase'
```

The *prefix* may be any *bytes-like object*.

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

Added in version 3.9.

bytes.**removesuffix**(*suffix*, /)

bytearray.**removesuffix**(*suffix*, /)

If the binary data ends with the *suffix* string and that *suffix* is not empty, return `bytes[:-len(suffix)]`. Otherwise, return a copy of the original binary data:

```
>>> b'MiscTests'.removesuffix(b'Tests')
b'Misc'
>>> b'TmpDirMixin'.removesuffix(b'Tests')
b'TmpDirMixin'
```

The *suffix* may be any *bytes-like object*.

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

Added in version 3.9.

bytes.**decode**(*encoding='utf-8'*, *errors='strict'*)

bytearray.**decode**(*encoding='utf-8'*, *errors='strict'*)

Return the bytes decoded to a *str*.

encoding defaults to `'utf-8'`; see *Standard Encodings* for possible values.

errors controls how decoding errors are handled. If `'strict'` (the default), a *UnicodeError* exception is raised. Other possible values are `'ignore'`, `'replace'`, and any other name registered via *codecs.register_error()*. See *Error Handlers* for details.

For performance reasons, the value of *errors* is not checked for validity unless a decoding error actually occurs, *Python Development Mode* is enabled or a debug build is used.

Note

Passing the *encoding* argument to *str* allows decoding any *bytes-like object* directly, without needing to make a temporary `bytes` or `bytearray` object.

Changed in version 3.1: Added support for keyword arguments.

Changed in version 3.9: The value of the *errors* argument is now checked in *Python Development Mode* and in debug mode.

`bytes.`**`endswith`**(*suffix*[, *start*[, *end*]])

`bytearray.`**`endswith`**(*suffix*[, *start*[, *end*]])

Return `True` if the binary data ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The suffix(es) to search for may be any *bytes-like object*.

`bytes.`**`find`**(*sub*[, *start*[, *end*]])

`bytearray.`**`find`**(*sub*[, *start*[, *end*]])

Return the lowest index in the data where the subsequence *sub* is found, such that *sub* is contained in the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

Note

The *find()* method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> b'Py' in b'Python'
True
```

Changed in version 3.3: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.`**`index`**(*sub*[, *start*[, *end*]])

`bytearray.`**`index`**(*sub*[, *start*[, *end*]])

Like *find()*, but raise *ValueError* when the subsequence is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

Changed in version 3.3: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.`**`join`**(*iterable*)

`bytearray.`**`join`**(*iterable*)

Return a bytes or bytearray object which is the concatenation of the binary data sequences in *iterable*. A *TypeError* will be raised if there are any values in *iterable* that are not *bytes-like objects*, including *str* objects. The separator between elements is the contents of the bytes or bytearray object providing this method.

`static` `bytes.`**`maketrans`**(*from*, *to*)

`static` `bytearray.`**`maketrans`**(*from*, *to*)

This static method returns a translation table usable for *bytes.translate()* that will map each character in *from* into the character at the same position in *to*; *from* and *to* must both be *bytes-like objects* and have the same length.

Added in version 3.1.

`bytes.`**`partition`**(*sep*)

`bytearray.`**`partition`**(*sep*)

Split the sequence at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing a copy of the original sequence, followed by two empty bytes or bytearray objects.

The separator to search for may be any *bytes-like object*.

`bytes.`**`replace`**(*old*, *new*[, *count*])

bytearray.**replace**(*old*, *new*[, *count*])

Return a copy of the sequence with all occurrences of subsequence *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

The subsequence to search for and its replacement may be any *bytes-like object*.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**rfind**(*sub*[, *start*[, *end*]])

bytearray.**rfind**(*sub*[, *start*[, *end*]])

Return the highest index in the sequence where the subsequence *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

Changed in version 3.3: Also accept an integer in the range 0 to 255 as the subsequence.

bytes.**rindex**(*sub*[, *start*[, *end*]])

bytearray.**rindex**(*sub*[, *start*[, *end*]])

Like *rfind()* but raises *ValueError* when the subsequence *sub* is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

Changed in version 3.3: Also accept an integer in the range 0 to 255 as the subsequence.

bytes.**rpartition**(*sep*)

bytearray.**rpartition**(*sep*)

Split the sequence at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty bytes or bytearray objects, followed by a copy of the original sequence.

The separator to search for may be any *bytes-like object*.

bytes.**startswith**(*prefix*[, *start*[, *end*]])

bytearray.**startswith**(*prefix*[, *start*[, *end*]])

Return `True` if the binary data starts with the specified *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The prefix(es) to search for may be any *bytes-like object*.

bytes.**translate**(*table*, /, *delete=b''*)

bytearray.**translate**(*table*, /, *delete=b''*)

Return a copy of the bytes or bytearray object where all bytes occurring in the optional argument *delete* are removed, and the remaining bytes have been mapped through the given translation table, which must be a bytes object of length 256.

You can use the *bytes.maketrans()* method to create a translation table.

Set the *table* argument to `None` for translations that only delete characters:

```
>>> b'read this short text'.translate(None, b'aeiou')
b'rd ths shrt txt'
```

Changed in version 3.6: *delete* is now supported as a keyword argument.

The following methods on bytes and bytearray objects have default behaviours that assume the use of ASCII compatible binary formats, but can still be used with arbitrary binary data by passing appropriate arguments. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

bytes.**center**(*width*[, *fillbyte*])

bytearray.**center**(*width*[, *fillbyte*])

Return a copy of the object centered in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**ljust**(*width*[, *fillbyte*])

bytearray.**ljust**(*width*[, *fillbyte*])

Return a copy of the object left justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**lstrip**([*chars*])

bytearray.**lstrip**([*chars*])

Return a copy of the sequence with specified leading bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.lstrip()
b'spacious   '
>>> b'www.example.com'.lstrip(b'cmowz.')
b'example.com'
```

The binary sequence of byte values to remove may be any *bytes-like object*. See *removeprefix()* for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> b'Arthur: three!'.lstrip(b'Arthur: ')
b'ee!'
>>> b'Arthur: three!'.removeprefix(b'Arthur: ')
b'three!'
```

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**rjust**(*width*[, *fillbyte*])

bytearray.**rjust**(*width*[, *fillbyte*])

Return a copy of the object right justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**rsplit**(*sep=None*, *maxsplit=-1*)

bytearray.**rsplit**(*sep=None*, *maxsplit=-1*)

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any subsequence consisting solely of ASCII whitespace is a separator. Except for splitting from the right, *rsplit()* behaves like *split()* which is described in detail below.

bytes.**rstrip**([*chars*])

bytearray.**rstrip**([*chars*])

Return a copy of the sequence with specified trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.rstrip()
b'   spacious'
>>> b'mississippi'.rstrip(b'ipz')
b'mississ'
```

The binary sequence of byte values to remove may be any *bytes-like object*. See *removesuffix()* for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> b'Monty Python'.rstrip(b' Python')
b'M'
>>> b'Monty Python'.removesuffix(b' Python')
b'Monty'
```

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**split**(*sep=None*, *maxsplit=-1*)

bytearray.**split**(*sep=None*, *maxsplit=-1*)

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given and non-negative, at most *maxsplit* splits are done (thus, the list will have at most `maxsplit+1` elements). If *maxsplit* is not specified or is `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty subsequences (for example, `b'1,,2'.split(b',')` returns `[b'1', b'', b'2']`). The *sep* argument may consist of a multibyte sequence as a single delimiter. Splitting an empty sequence with a specified separator returns `[b'']` or `[bytearray(b'')]` depending on the type of object being split. The *sep* argument may be any *bytes-like object*.

For example:

```
>>> b'1,2,3'.split(b',')
[b'1', b'2', b'3']
>>> b'1,2,3'.split(b',', maxsplit=1)
[b'1', b'2,3']
```

(continues on next page)

(continued from previous page)

```
>>> b'1,2,,3,'.split(b',')
[b'1', b'2', b'', b'3', b'']
>>> b'1<>2<>3<4'.split(b'<>')
[b'1', b'2', b'3<4']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive ASCII whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the sequence has leading or trailing whitespace. Consequently, splitting an empty sequence or a sequence consisting solely of ASCII whitespace without a specified separator returns `[]`.

For example:

```
>>> b'1 2 3'.split()
[b'1', b'2', b'3']
>>> b'1 2 3'.split(maxsplit=1)
[b'1', b'2 3']
>>> b'   1   2   3   '.split()
[b'1', b'2', b'3']
```

`bytes.`**`strip`**`(`[*chars*]`)`

`bytearray.`**`strip`**`(`[*chars*]`)`

Return a copy of the sequence with specified leading and trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.strip()
b'spacious'
>>> b'www.example.com'.strip(b'cmowz.')
b'example'
```

The binary sequence of byte values to remove may be any *bytes-like object*.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

The following methods on bytes and bytearray objects assume the use of ASCII compatible binary formats and should not be applied to arbitrary binary data. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

`bytes.`**`capitalize`**`()`

`bytearray.`**`capitalize`**`()`

Return a copy of the sequence with each byte interpreted as an ASCII character, and the first byte capitalized and the rest lowercased. Non-ASCII byte values are passed through unchanged.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.`**`expandtabs`**`(`*tabsize*=*8*`)`

bytearray.**expandtabs**(*tabsize=8*)

Return a copy of the sequence where all ASCII tab characters are replaced by one or more ASCII spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* bytes (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the sequence, the current column is set to zero and the sequence is examined byte by byte. If the byte is an ASCII tab character (`b'\t'`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the current byte is an ASCII newline (`b'\n'`) or carriage return (`b'\r'`), it is copied and the current column is reset to zero. Any other byte value is copied unchanged and the current column is incremented by one regardless of how the byte value is represented when printed:

```
>>> b'01\t012\t0123\t01234'.expandtabs()
b'01      012     0123    01234'
>>> b'01\t012\t0123\t01234'.expandtabs(4)
b'01  012 0123    01234'
```

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**isalnum**()

bytearray.**isalnum**()

Return `True` if all bytes in the sequence are alphabetical ASCII characters or ASCII decimal digits and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`. ASCII decimal digits are those byte values in the sequence `b'0123456789'`.

For example:

```
>>> b'ABCabc1'.isalnum()
True
>>> b'ABC abc1'.isalnum()
False
```

bytes.**isalpha**()

bytearray.**isalpha**()

Return `True` if all bytes in the sequence are alphabetic ASCII characters and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

For example:

```
>>> b'ABCabc'.isalpha()
True
>>> b'ABCabc1'.isalpha()
False
```

bytes.**isascii**()

bytearray.**isascii**()

Return `True` if the sequence is empty or all bytes in the sequence are ASCII, `False` otherwise. ASCII bytes are in the range 0-0x7F.

Added in version 3.7.

bytes.**isdigit**()

bytearray.**isdigit**()

Return `True` if all bytes in the sequence are ASCII decimal digits and the sequence is not empty, `False` otherwise. ASCII decimal digits are those byte values in the sequence `b'0123456789'`.

For example:

```
>>> b'1234'.isdigit()
True
>>> b'1.23'.isdigit()
False
```

bytes.**islower**()

bytearray.**islower**()

Return `True` if there is at least one lowercase ASCII character in the sequence and no uppercase ASCII characters, `False` otherwise.

For example:

```
>>> b'hello world'.islower()
True
>>> b'Hello world'.islower()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

bytes.**isspace**()

bytearray.**isspace**()

Return `True` if all bytes in the sequence are ASCII whitespace and the sequence is not empty, `False` otherwise. ASCII whitespace characters are those byte values in the sequence `b' \t\n\r\x0b\f'` (space, tab, newline, carriage return, vertical tab, form feed).

bytes.**istitle**()

bytearray.**istitle**()

Return `True` if the sequence is ASCII titlecase and the sequence is not empty, `False` otherwise. See *bytes.title()* for more details on the definition of "titlecase".

For example:

```
>>> b'Hello World'.istitle()
True
>>> b'Hello world'.istitle()
False
```

bytes.**isupper**()

bytearray.**isupper**()

Return `True` if there is at least one uppercase alphabetic ASCII character in the sequence and no lowercase ASCII characters, `False` otherwise.

For example:

```
>>> b'HELLO WORLD'.isupper()
True
>>> b'Hello world'.isupper()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

bytes.**lower**()

bytearray.**lower**()

Return a copy of the sequence with all the uppercase ASCII characters converted to their corresponding lowercase counterpart.

For example:

```
>>> b'Hello World'.lower()
b'hello world'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**splitlines**(*keepends=False*)

bytearray.**splitlines**(*keepends=False*)

Return a list of the lines in the binary sequence, breaking at ASCII line boundaries. This method uses the *universal newlines* approach to splitting lines. Line breaks are not included in the resulting list unless *keepends* is given and true.

For example:

```
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines()
[b'ab c', b'', b'de fg', b'kl']
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
[b'ab c\n', b'\n', b'de fg\r', b'kl\r\n']
```

Unlike *split()* when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> b"".split(b'\n'), b"Two lines\n".split(b'\n')
([b''], [b'Two lines', b''])
>>> b"".splitlines(), b"One line\n".splitlines()
([], [b'One line'])
```

bytes.**swapcase**()

bytearray.**swapcase**()

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart and vice-versa.

For example:

```
>>> b'Hello World'.swapcase()
b'hELLO wORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Unlike *str.swapcase()*, it is always the case that `bin.swapcase().swapcase() == bin` for the binary versions. Case conversions are symmetrical in ASCII, even though that is not generally true for arbitrary Unicode code points.

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**title**()

bytearray.**title**()

Return a titlecased version of the binary sequence where words start with an uppercase ASCII character and the remaining characters are lowercase. Uncased byte values are left unmodified.

For example:

```
>>> b'Hello world'.title()
b'Hello World'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. All other byte values are uncased.

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> b"they're bill's friends from the UK".title()
b"They'Re Bill'S Friends From The Uk"
```

A workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(rb"[A-Za-z]+('[A-Za-z]+)?",
...                   lambda mo: mo.group(0)[0:1].upper() +
...                              mo.group(0)[1:].lower(),
...                   s)
...
>>> titlecase(b"they're bill's friends.")
b"They're Bill's Friends."
```

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**upper**()

bytearray.**upper**()

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart.

For example:

```
>>> b'Hello World'.upper()
b'HELLO WORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.`**`zfill`**`(`*width*`)`

`bytearray.`**`zfill`**`(`*width*`)`

Return a copy of the sequence left filled with ASCII `b'0'` digits to make a sequence of length *width*. A leading sign prefix (`b'+'`/`b'-'`) is handled by inserting the padding *after* the sign character rather than before. For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(seq)`.

For example:

```
>>> b"42".zfill(5)
b'00042'
>>> b"-42".zfill(5)
b'-0042'
```

> **Note**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

4.9.4 `printf`-style Bytes Formatting

> **Note**
>
> The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). If the value being printed may be a tuple or dictionary, wrap it in a tuple.

Bytes objects (`bytes`/`bytearray`) have one unique built-in operation: the `%` operator (modulo). This is also known as the bytes *formatting* or *interpolation* operator. Given `format % values` (where *format* is a bytes object), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to using the `sprintf()` in the C language.

If *format* requires a single argument, *values* may be a single non-tuple object.[Page 63, 5] Otherwise, *values* must be a tuple with exactly the number of items specified by the format bytes object, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the bytes object *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print(b'%(language)s has %(number)03d quote types.' %
...       {b'language': b"Python", b"number": 2})
b'Python has 002 quote types.'
```

In this case no `*` specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

Flag	Meaning
`'#'`	The value conversion will use the "alternate form" (where defined below).
`'0'`	The conversion will be zero padded for numeric values.
`'-'`	The converted value is left adjusted (overrides the `'0'` conversion if both are given).
`' '`	(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
`'+'`	A sign character (`'+'` or `'-'`) will precede the conversion (overrides a "space" flag).

A length modifier (`h`, `l`, or `L`) may be present, but is ignored as it is not necessary for Python – so e.g. `%ld` is identical to `%d`.

The conversion types are:

Conversion	Meaning	Notes
`'d'`	Signed integer decimal.	
`'i'`	Signed integer decimal.	
`'o'`	Signed octal value.	(1)
`'u'`	Obsolete type – it is identical to `'d'`.	(8)
`'x'`	Signed hexadecimal (lowercase).	(2)
`'X'`	Signed hexadecimal (uppercase).	(2)
`'e'`	Floating-point exponential format (lowercase).	(3)
`'E'`	Floating-point exponential format (uppercase).	(3)
`'f'`	Floating-point decimal format.	(3)
`'F'`	Floating-point decimal format.	(3)
`'g'`	Floating-point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
`'G'`	Floating-point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
`'c'`	Single byte (accepts integer or single byte objects).	
`'b'`	Bytes (any object that follows the buffer protocol or has `__bytes__()`).	(5)
`'s'`	`'s'` is an alias for `'b'` and should only be used for Python2/3 code bases.	(6)
`'a'`	Bytes (converts any Python object using `repr(obj).encode('ascii', 'backslashreplace')`).	(5)
`'r'`	`'r'` is an alias for `'a'` and should only be used for Python2/3 code bases.	(7)
`'%'`	No argument is converted, results in a `'%'` character in the result.	

Notes:

(1) The alternate form causes a leading octal specifier (`'0o'`) to be inserted before the first digit.

(2) The alternate form causes a leading `'0x'` or `'0X'` (depending on whether the `'x'` or `'X'` format was used) to be inserted before the first digit.

(3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.

The precision determines the number of digits after the decimal point and defaults to 6.

(4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

(5) If precision is `N`, the output is truncated to `N` characters.

(6) `b'%s'` is deprecated, but will not be removed during the 3.x series.

(7) `b'%r'` is deprecated, but will not be removed during the 3.x series.

(8) See **PEP 237**.

Note

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

See also

PEP 461 - Adding % formatting to bytes and bytearray

Added in version 3.5.

4.9.5 Memory Views

memoryview objects allow Python code to access the internal data of an object that supports the buffer protocol without copying.

class memoryview(*object*)

Create a *memoryview* that references *object*. *object* must support the buffer protocol. Built-in objects that support the buffer protocol include *bytes* and *bytearray*.

A *memoryview* has the notion of an *element*, which is the atomic memory unit handled by the originating *object*. For many simple types such as *bytes* and *bytearray*, an element is a single byte, but other types such as *array.array* may have bigger elements.

`len(view)` is equal to the length of *tolist*, which is the nested list representation of the view. If `view.ndim = 1`, this is equal to the number of elements in the view.

Changed in version 3.12: If `view.ndim == 0`, `len(view)` now raises *TypeError* instead of returning 1.

The *itemsize* attribute will give you the number of bytes in a single element.

A *memoryview* supports slicing and indexing to expose its data. One-dimensional slicing will result in a subview:

```
>>> v = memoryview(b'abcefg')
>>> v[1]
98
>>> v[-1]
103
>>> v[1:4]
<memory at 0x7f3ddc9f4350>
>>> bytes(v[1:4])
b'bce'
```

If *format* is one of the native format specifiers from the *struct* module, indexing with an integer or a tuple of integers is also supported and returns a single *element* with the correct type. One-dimensional memoryviews can be indexed with an integer or a one-integer tuple. Multi-dimensional memoryviews can be indexed with

tuples of exactly *ndim* integers where *ndim* is the number of dimensions. Zero-dimensional memoryviews can be indexed with the empty tuple.

Here is an example with a non-byte format:

```
>>> import array
>>> a = array.array('l', [-11111111, 22222222, -33333333, 44444444])
>>> m = memoryview(a)
>>> m[0]
-11111111
>>> m[-1]
44444444
>>> m[::2].tolist()
[-11111111, -33333333]
```

If the underlying object is writable, the memoryview supports one-dimensional slice assignment. Resizing is not allowed:

```
>>> data = bytearray(b'abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = ord(b'z')
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = b'123'
>>> data
bytearray(b'z123fg')
>>> v[2:3] = b'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview assignment: lvalue and rvalue have different structures
>>> v[2:6] = b'spam'
>>> data
bytearray(b'z1spam')
```

One-dimensional memoryviews of *hashable* (read-only) types with formats 'B', 'b' or 'c' are also hashable. The hash is defined as `hash(m) == hash(m.tobytes())`:

```
>>> v = memoryview(b'abcefg')
>>> hash(v) == hash(b'abcefg')
True
>>> hash(v[2:4]) == hash(b'ce')
True
>>> hash(v[::-2]) == hash(b'abcefg'[::-2])
True
```

Changed in version 3.3: One-dimensional memoryviews can now be sliced. One-dimensional memoryviews with formats 'B', 'b' or 'c' are now *hashable*.

Changed in version 3.4: memoryview is now registered automatically with *collections.abc.Sequence*

Changed in version 3.5: memoryviews can now be indexed with tuple of integers.

memoryview has several methods:

__eq__(*exporter*)

A memoryview and a **PEP 3118** exporter are equal if their shapes are equivalent and if all corresponding values are equal when the operands' respective format codes are interpreted using *struct* syntax.

For the subset of *struct* format strings currently supported by *tolist()*, `v` and `w` are equal if `v.tolist() == w.tolist()`:

```
>>> import array
>>> a = array.array('I', [1, 2, 3, 4, 5])
>>> b = array.array('d', [1.0, 2.0, 3.0, 4.0, 5.0])
>>> c = array.array('b', [5, 3, 1])
>>> x = memoryview(a)
>>> y = memoryview(b)
>>> x == a == y == b
True
>>> x.tolist() == a.tolist() == y.tolist() == b.tolist()
True
>>> z = y[::-2]
>>> z == c
True
>>> z.tolist() == c.tolist()
True
```

If either format string is not supported by the *struct* module, then the objects will always compare as unequal (even if the format strings and buffer contents are identical):

```
>>> from ctypes import BigEndianStructure, c_long
>>> class BEPoint(BigEndianStructure):
...     _fields_ = [("x", c_long), ("y", c_long)]
...
>>> point = BEPoint(100, 200)
>>> a = memoryview(point)
>>> b = memoryview(point)
>>> a == point
False
>>> a == b
False
```

Note that, as with floating-point numbers, `v is w` does *not* imply `v == w` for memoryview objects.

Changed in version 3.3: Previous versions compared the raw memory disregarding the item format and the logical array structure.

tobytes(*order='C'*)

Return the data in the buffer as a bytestring. This is equivalent to calling the *bytes* constructor on the memoryview.

```
>>> m = memoryview(b"abc")
>>> m.tobytes()
b'abc'
>>> bytes(m)
b'abc'
```

For non-contiguous arrays the result is equal to the flattened list representation with all elements converted to bytes. *tobytes()* supports all format strings, including those that are not in *struct* module syntax.

Added in version 3.8: *order* can be {'C', 'F', 'A'}. When *order* is 'C' or 'F', the data of the original array is converted to C or Fortran order. For contiguous views, 'A' returns an exact copy of the physical memory. In particular, in-memory Fortran order is preserved. For non-contiguous views, the data is converted to C first. *order=None* is the same as *order='C'*.

hex([*sep*[, *bytes_per_sep*]])

Return a string object containing two hexadecimal digits for each byte in the buffer.

```
>>> m = memoryview(b"abc")
>>> m.hex()
```

(continues on next page)

(continued from previous page)

```
'616263'
```

Added in version 3.5.

Changed in version 3.8: Similar to *bytes.hex()*, *memoryview.hex()* now supports optional *sep* and *bytes_per_sep* parameters to insert separators between bytes in the hex output.

tolist()

Return the data in the buffer as a list of elements.

```
>>> memoryview(b'abc').tolist()
[97, 98, 99]
>>> import array
>>> a = array.array('d', [1.1, 2.2, 3.3])
>>> m = memoryview(a)
>>> m.tolist()
[1.1, 2.2, 3.3]
```

Changed in version 3.3: *tolist()* now supports all single character native formats in *struct* module syntax as well as multi-dimensional representations.

toreadonly()

Return a readonly version of the memoryview object. The original memoryview object is unchanged.

```
>>> m = memoryview(bytearray(b'abc'))
>>> mm = m.toreadonly()
>>> mm.tolist()
[97, 98, 99]
>>> mm[0] = 42
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot modify read-only memory
>>> m[0] = 43
>>> mm.tolist()
[43, 98, 99]
```

Added in version 3.8.

release()

Release the underlying buffer exposed by the memoryview object. Many objects take special actions when a view is held on them (for example, a *bytearray* would temporarily forbid resizing); therefore, calling release() is handy to remove these restrictions (and free any dangling resources) as soon as possible.

After this method has been called, any further operation on the view raises a *ValueError* (except *release()* itself which can be called multiple times):

```
>>> m = memoryview(b'abc')
>>> m.release()
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

The context management protocol can be used for a similar effect, using the `with` statement:

```
>>> with memoryview(b'abc') as m:
...     m[0]
...
97
```

(continues on next page)

(continued from previous page)

```
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

Added in version 3.2.

cast (*format*[, *shape*])

Cast a memoryview to a new format or shape. *shape* defaults to `[byte_length//new_itemsize]`, which means that the result view will be one-dimensional. The return value is a new memoryview, but the buffer itself is not copied. Supported casts are 1D -> C-*contiguous* and C-contiguous -> 1D.

The destination format is restricted to a single element native format in *struct* syntax. One of the formats must be a byte format ('B', 'b' or 'c'). The byte length of the result must be the same as the original length. Note that all byte lengths may depend on the operating system.

Cast 1D/long to 1D/unsigned bytes:

```
>>> import array
>>> a = array.array('l', [1,2,3])
>>> x = memoryview(a)
>>> x.format
'l'
>>> x.itemsize
8
>>> len(x)
3
>>> x.nbytes
24
>>> y = x.cast('B')
>>> y.format
'B'
>>> y.itemsize
1
>>> len(y)
24
>>> y.nbytes
24
```

Cast 1D/unsigned bytes to 1D/char:

```
>>> b = bytearray(b'zyz')
>>> x = memoryview(b)
>>> x[0] = b'a'
Traceback (most recent call last):
  ...
TypeError: memoryview: invalid type for format 'B'
>>> y = x.cast('c')
>>> y[0] = b'a'
>>> b
bytearray(b'ayz')
```

Cast 1D/bytes to 3D/ints to 1D/signed char:

```
>>> import struct
>>> buf = struct.pack("i"*12, *list(range(12)))
>>> x = memoryview(buf)
>>> y = x.cast('i', shape=[2,2,3])
```

(continues on next page)

(continued from previous page)

```
>>> y.tolist()
[[[0, 1, 2], [3, 4, 5]], [[6, 7, 8], [9, 10, 11]]]
>>> y.format
'i'
>>> y.itemsize
4
>>> len(y)
2
>>> y.nbytes
48
>>> z = y.cast('b')
>>> z.format
'b'
>>> z.itemsize
1
>>> len(z)
48
>>> z.nbytes
48
```

Cast 1D/unsigned long to 2D/unsigned long:

```
>>> buf = struct.pack("L"*6, *list(range(6)))
>>> x = memoryview(buf)
>>> y = x.cast('L', shape=[2,3])
>>> len(y)
2
>>> y.nbytes
48
>>> y.tolist()
[[0, 1, 2], [3, 4, 5]]
```

Added in version 3.3.

Changed in version 3.5: The source format is no longer restricted when casting to a byte view.

There are also several readonly attributes available:

obj

The underlying object of the memoryview:

```
>>> b  = bytearray(b'xyz')
>>> m = memoryview(b)
>>> m.obj is b
True
```

Added in version 3.3.

nbytes

`nbytes == product(shape) * itemsize == len(m.tobytes())`. This is the amount of space in bytes that the array would use in a contiguous representation. It is not necessarily equal to `len(m)`:

```
>>> import array
>>> a = array.array('i', [1,2,3,4,5])
>>> m = memoryview(a)
>>> len(m)
5
>>> m.nbytes
```

(continues on next page)

(continued from previous page)

```
20
>>> y = m[::2]
>>> len(y)
3
>>> y.nbytes
12
>>> len(y.tobytes())
12
```

Multi-dimensional arrays:

```
>>> import struct
>>> buf = struct.pack("d"*12, *[1.5*x for x in range(12)])
>>> x = memoryview(buf)
>>> y = x.cast('d', shape=[3,4])
>>> y.tolist()
[[0.0, 1.5, 3.0, 4.5], [6.0, 7.5, 9.0, 10.5], [12.0, 13.5, 15.0, 16.5]]
>>> len(y)
3
>>> y.nbytes
96
```

Added in version 3.3.

readonly

A bool indicating whether the memory is read only.

format

A string containing the format (in *struct* module style) for each element in the view. A memoryview can be created from exporters with arbitrary format strings, but some methods (e.g. *tolist()*) are restricted to native single element formats.

Changed in version 3.3: format `'B'` is now handled according to the struct module syntax. This means that `memoryview(b'abc')[0] == b'abc'[0] == 97`.

itemsize

The size in bytes of each element of the memoryview:

```
>>> import array, struct
>>> m = memoryview(array.array('H', [32000, 32001, 32002]))
>>> m.itemsize
2
>>> m[0]
32000
>>> struct.calcsize('H') == m.itemsize
True
```

ndim

An integer indicating how many dimensions of a multi-dimensional array the memory represents.

shape

A tuple of integers the length of *ndim* giving the shape of the memory as an N-dimensional array.

Changed in version 3.3: An empty tuple instead of `None` when ndim = 0.

strides

A tuple of integers the length of *ndim* giving the size in bytes to access each element for each dimension of the array.

Changed in version 3.3: An empty tuple instead of `None` when ndim = 0.

suboffsets

Used internally for PIL-style arrays. The value is informational only.

c_contiguous

A bool indicating whether the memory is C-*contiguous*.

Added in version 3.3.

f_contiguous

A bool indicating whether the memory is Fortran *contiguous*.

Added in version 3.3.

contiguous

A bool indicating whether the memory is *contiguous*.

Added in version 3.3.

4.10 Set Types — `set`, `frozenset`

A *set* object is an unordered collection of distinct *hashable* objects. Common uses include membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference. (For other containers see the built-in `dict`, `list`, and `tuple` classes, and the `collections` module.)

Like other collections, sets support `x in set`, `len(set)`, and `for x in set`. Being an unordered collection, sets do not record element position or order of insertion. Accordingly, sets do not support indexing, slicing, or other sequence-like behavior.

There are currently two built-in set types, `set` and `frozenset`. The `set` type is mutable — the contents can be changed using methods like `add()` and `remove()`. Since it is mutable, it has no hash value and cannot be used as either a dictionary key or as an element of another set. The `frozenset` type is immutable and *hashable* — its contents cannot be altered after it is created; it can therefore be used as a dictionary key or as an element of another set.

Non-empty sets (not frozensets) can be created by placing a comma-separated list of elements within braces, for example: `{'jack', 'sjoerd'}`, in addition to the `set` constructor.

The constructors for both classes work the same:

class set([*iterable*])

class frozenset([*iterable*])

Return a new set or frozenset object whose elements are taken from *iterable*. The elements of a set must be *hashable*. To represent sets of sets, the inner sets must be `frozenset` objects. If *iterable* is not specified, a new empty set is returned.

Sets can be created by several means:

- Use a comma-separated list of elements within braces: `{'jack', 'sjoerd'}`
- Use a set comprehension: `{c for c in 'abracadabra' if c not in 'abc'}`
- Use the type constructor: `set()`, `set('foobar')`, `set(['a', 'b', 'foo'])`

Instances of `set` and `frozenset` provide the following operations:

len(s)

Return the number of elements in set *s* (cardinality of *s*).

x in s

Test *x* for membership in *s*.

x not in s

Test *x* for non-membership in *s*.

isdisjoint(*other*)

Return `True` if the set has no elements in common with *other*. Sets are disjoint if and only if their intersection is the empty set.

issubset(*other*)

set <= other

Test whether every element in the set is in *other*.

set < other

Test whether the set is a proper subset of *other*, that is, `set <= other and set != other`.

issuperset(*other*)

set >= other

Test whether every element in *other* is in the set.

set > other

Test whether the set is a proper superset of *other*, that is, `set >= other and set != other`.

union(**others*)

set | other | ...

Return a new set with elements from the set and all others.

intersection(**others*)

set & other & ...

Return a new set with elements common to the set and all others.

difference(**others*)

set - other - ...

Return a new set with elements in the set that are not in the others.

symmetric_difference(*other*)

set ^ other

Return a new set with elements in either the set or *other* but not both.

copy()

Return a shallow copy of the set.

Note, the non-operator versions of *union()*, *intersection()*, *difference()*, *symmetric_difference()*, *issubset()*, and *issuperset()* methods will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `set('abc') & 'cbs'` in favor of the more readable `set('abc').intersection('cbs')`.

Both *set* and *frozenset* support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

Instances of *set* are compared to instances of *frozenset* based on their members. For example, `set('abc') == frozenset('abc')` returns `True` and so does `set('abc') in set([frozenset('abc')])`.

The subset and equality comparisons do not generalize to a total ordering function. For example, any two nonempty disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False`: `a<b`, `a==b`, or `a>b`.

Since sets only define partial ordering (subset relationships), the output of the *list.sort()* method is undefined for lists of sets.

Set elements, like dictionary keys, must be *hashable*.

Binary operations that mix *set* instances with *frozenset* return the type of the first operand. For example: `frozenset('ab') | set('bc')` returns an instance of *frozenset*.

The following table lists operations available for *set* that do not apply to immutable instances of *frozenset*:

update(**others*)

set |= other | ...

Update the set, adding elements from all others.

intersection_update(**others*)

set &= other & ...

Update the set, keeping only elements found in it and all others.

difference_update(**others*)

set -= other | ...

Update the set, removing elements found in others.

symmetric_difference_update(*other*)

set ^= other

Update the set, keeping only elements found in either set, but not in both.

add(*elem*)

Add element *elem* to the set.

remove(*elem*)

Remove element *elem* from the set. Raises *KeyError* if *elem* is not contained in the set.

discard(*elem*)

Remove element *elem* from the set if it is present.

pop()

Remove and return an arbitrary element from the set. Raises *KeyError* if the set is empty.

clear()

Remove all elements from the set.

Note, the non-operator versions of the *update()*, *intersection_update()*, *difference_update()*, and *symmetric_difference_update()* methods will accept any iterable as an argument.

Note, the *elem* argument to the `__contains__()`, *remove()*, and *discard()* methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

4.11 Mapping Types — `dict`

A *mapping* object maps *hashable* values to arbitrary objects. Mappings are mutable objects. There is currently only one standard mapping type, the *dictionary*. (For other containers see the built-in *list*, *set*, and *tuple* classes, and the *collections* module.)

A dictionary's keys are *almost* arbitrary values. Values that are not *hashable*, that is, values containing lists, dictionaries or other mutable types (that are compared by value rather than by object identity) may not be used as keys. Values that compare equal (such as `1`, `1.0`, and `True`) can be used interchangeably to index the same dictionary entry.

class dict(***kwargs*)

class dict(*mapping*, ***kwargs*)

class dict(*iterable*, ***kwargs*)

Return a new dictionary initialized from an optional positional argument and a possibly empty set of keyword arguments.

Dictionaries can be created by several means:

- Use a comma-separated list of `key: value` pairs within braces: `{'jack': 4098, 'sjoerd': 4127}` or `{4098: 'jack', 4127: 'sjoerd'}`

- Use a dict comprehension: `{}`, `{x: x ** 2 for x in range(10)}`
- Use the type constructor: `dict()`, `dict([('foo', 100), ('bar', 200)])`, `dict(foo=100, bar=200)`

If no positional argument is given, an empty dictionary is created. If a positional argument is given and it defines a `keys()` method, a dictionary is created by calling `__getitem__()` on the argument with each returned key from the method. Otherwise, the positional argument must be an *iterable* object. Each item in the iterable must itself be an iterable with exactly two elements. The first element of each item becomes a key in the new dictionary, and the second element the corresponding value. If a key occurs more than once, the last value for that key becomes the corresponding value in the new dictionary.

If keyword arguments are given, the keyword arguments and their values are added to the dictionary created from the positional argument. If a key being added is already present, the value from the keyword argument replaces the value from the positional argument.

Providing keyword arguments as in the first example only works for keys that are valid Python identifiers. Otherwise, any valid keys can be used.

Dictionaries compare equal if and only if they have the same `(key, value)` pairs (regardless of ordering). Order comparisons ('<', '<=', '>=', '>') raise *TypeError*. To illustrate dictionary creation and equality, the following examples all return a dictionary equal to `{"one": 1, "two": 2, "three": 3}`:

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> f = dict({'one': 1, 'three': 3}, two=2)
>>> a == b == c == d == e == f
True
```

Providing keyword arguments as in the first example only works for keys that are valid Python identifiers. Otherwise, any valid keys can be used.

Dictionaries preserve insertion order. Note that updating a key does not affect the order. Keys added after deletion are inserted at the end.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(d)
['one', 'two', 'three', 'four']
>>> list(d.values())
[1, 2, 3, 4]
>>> d["one"] = 42
>>> d
{'one': 42, 'two': 2, 'three': 3, 'four': 4}
>>> del d["two"]
>>> d["two"] = None
>>> d
{'one': 42, 'three': 3, 'four': 4, 'two': None}
```

Changed in version 3.7: Dictionary order is guaranteed to be insertion order. This behavior was an implementation detail of CPython from 3.6.

These are the operations that dictionaries support (and therefore, custom mapping types should support too):

`list(d)`

Return a list of all the keys used in the dictionary *d*.

`len(d)`

Return the number of items in the dictionary *d*.

d[key]

Return the item of *d* with key *key*. Raises a *KeyError* if *key* is not in the map.

If a subclass of dict defines a method __missing__() and *key* is not present, the d[key] operation calls that method with the key *key* as argument. The d[key] operation then returns or raises whatever is returned or raised by the __missing__(key) call. No other operations or methods invoke __missing__(). If __missing__() is not defined, *KeyError* is raised. __missing__() must be a method; it cannot be an instance variable:

```
>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
...
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

The example above shows part of the implementation of *collections.Counter*. A different __missing__ method is used by *collections.defaultdict*.

d[key] = value

Set d[key] to *value*.

del d[key]

Remove d[key] from *d*. Raises a *KeyError* if *key* is not in the map.

key in d

Return True if *d* has a key *key*, else False.

key not in d

Equivalent to not key in d.

iter(d)

Return an iterator over the keys of the dictionary. This is a shortcut for iter(d.keys()).

clear()

Remove all items from the dictionary.

copy()

Return a shallow copy of the dictionary.

classmethod fromkeys(*iterable*, *value=None*, /)

Create a new dictionary with keys from *iterable* and values set to *value*.

fromkeys() is a class method that returns a new dictionary. *value* defaults to None. All of the values refer to just a single instance, so it generally doesn't make sense for *value* to be a mutable object such as an empty list. To get distinct values, use a dict comprehension instead.

get(*key*, *default=None*, /)

Return the value for *key* if *key* is in the dictionary, else *default*. If *default* is not given, it defaults to None, so that this method never raises a *KeyError*.

items()

Return a new view of the dictionary's items ((key, value) pairs). See the *documentation of view objects*.

keys()

Return a new view of the dictionary's keys. See the *documentation of view objects*.

pop(*key*[, *default*])

If *key* is in the dictionary, remove it and return its value, else return *default*. If *default* is not given and *key* is not in the dictionary, a `KeyError` is raised.

popitem()

Remove and return a `(key, value)` pair from the dictionary. Pairs are returned in LIFO (last-in, first-out) order.

`popitem()` is useful to destructively iterate over a dictionary, as often used in set algorithms. If the dictionary is empty, calling `popitem()` raises a `KeyError`.

Changed in version 3.7: LIFO order is now guaranteed. In prior versions, `popitem()` would return an arbitrary key/value pair.

reversed(d)

Return a reverse iterator over the keys of the dictionary. This is a shortcut for `reversed(d.keys())`.

Added in version 3.8.

setdefault(*key*, *default=None*, /)

If *key* is in the dictionary, return its value. If not, insert *key* with a value of *default* and return *default*. *default* defaults to `None`.

update([*other*])

Update the dictionary with the key/value pairs from *other*, overwriting existing keys. Return `None`.

`update()` accepts either another object with a `keys()` method (in which case `__getitem__()` is called with every key returned from the method) or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs: `d.update(red=1, blue=2)`.

values()

Return a new view of the dictionary's values. See the *documentation of view objects*.

An equality comparison between one `dict.values()` view and another will always return `False`. This also applies when comparing `dict.values()` to itself:

```
>>> d = {'a': 1}
>>> d.values() == d.values()
False
```

d | other

Create a new dictionary with the merged keys and values of *d* and *other*, which must both be dictionaries. The values of *other* take priority when *d* and *other* share keys.

Added in version 3.9.

d |= other

Update the dictionary *d* with keys and values from *other*, which may be either a *mapping* or an *iterable* of key/value pairs. The values of *other* take priority when *d* and *other* share keys.

Added in version 3.9.

Dictionaries and dictionary views are reversible.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(reversed(d))
['four', 'three', 'two', 'one']
>>> list(reversed(d.values()))
[4, 3, 2, 1]
>>> list(reversed(d.items()))
[('four', 4), ('three', 3), ('two', 2), ('one', 1)]
```

Changed in version 3.8: Dictionaries are now reversible.

See also

types.MappingProxyType can be used to create a read-only view of a *dict*.

4.11.1 Dictionary view objects

The objects returned by *dict.keys()*, *dict.values()* and *dict.items()* are *view objects*. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes.

Dictionary views can be iterated over to yield their respective data, and support membership tests:

len(dictview)

Return the number of entries in the dictionary.

iter(dictview)

Return an iterator over the keys, values or items (represented as tuples of `(key, value)`) in the dictionary.

Keys and values are iterated over in insertion order. This allows the creation of `(value, key)` pairs using *zip()*: `pairs = zip(d.values(), d.keys())`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.items()]`.

Iterating views while adding or deleting entries in the dictionary may raise a *RuntimeError* or fail to iterate over all entries.

Changed in version 3.7: Dictionary order is guaranteed to be insertion order.

x in dictview

Return `True` if *x* is in the underlying dictionary's keys, values or items (in the latter case, *x* should be a `(key, value)` tuple).

reversed(dictview)

Return a reverse iterator over the keys, values or items of the dictionary. The view will be iterated in reverse order of the insertion.

Changed in version 3.8: Dictionary views are now reversible.

dictview.mapping

Return a *types.MappingProxyType* that wraps the original dictionary to which the view refers.

Added in version 3.10.

Keys views are set-like since their entries are unique and *hashable*. Items views also have set-like operations since the (key, value) pairs are unique and the keys are hashable. If all values in an items view are hashable as well, then the items view can interoperate with other sets. (Values views are not treated as set-like since the entries are generally not unique.) For set-like views, all of the operations defined for the abstract base class *collections.abc.Set* are available (for example, ==, <, or ^). While using set operators, set-like views accept any iterable as the other operand, unlike sets which only accept sets as the input.

An example of dictionary view usage:

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.keys()
>>> values = dishes.values()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
...
```

(continues on next page)

(continued from previous page)

```
>>> print(n)
504

>>> # keys and values are iterated over in the same order (insertion order)
>>> list(keys)
['eggs', 'sausage', 'bacon', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['bacon', 'spam']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
>>> keys ^ {'sausage', 'juice'} == {'juice', 'sausage', 'bacon', 'spam'}
True
>>> keys | ['juice', 'juice', 'juice'] == {'bacon', 'spam', 'juice'}
True

>>> # get back a read-only proxy for the original dictionary
>>> values.mapping
mappingproxy({'bacon': 1, 'spam': 500})
>>> values.mapping['spam']
500
```

4.12 Context Manager Types

Python's `with` statement supports the concept of a runtime context defined by a context manager. This is implemented using a pair of methods that allow user-defined classes to define a runtime context that is entered before the statement body is executed and exited when the statement ends:

`contextmanager.__enter__()`

Enter the runtime context and return either this object or another object related to the runtime context. The value returned by this method is bound to the identifier in the `as` clause of `with` statements using this context manager.

An example of a context manager that returns itself is a *file object*. File objects return themselves from __enter__() to allow *open()* to be used as the context expression in a `with` statement.

An example of a context manager that returns a related object is the one returned by *decimal.localcontext()*. These managers set the active decimal context to a copy of the original decimal context and then return the copy. This allows changes to be made to the current decimal context in the body of the `with` statement without affecting code outside the `with` statement.

`contextmanager.__exit__`(*exc_type*, *exc_val*, *exc_tb*)

Exit the runtime context and return a Boolean flag indicating if any exception that occurred should be suppressed. If an exception occurred while executing the body of the `with` statement, the arguments contain the exception type, value and traceback information. Otherwise, all three arguments are `None`.

Returning a true value from this method will cause the `with` statement to suppress the exception and continue execution with the statement immediately following the `with` statement. Otherwise the exception continues propagating after this method has finished executing. Exceptions that occur during execution of this method will replace any exception that occurred in the body of the `with` statement.

The exception passed in should never be reraised explicitly - instead, this method should return a false value to indicate that the method completed successfully and does not want to suppress the raised exception. This allows context management code to easily detect whether or not an `__exit__()` method has actually failed.

Python defines several context managers to support easy thread synchronisation, prompt closure of files or other objects, and simpler manipulation of the active decimal arithmetic context. The specific types are not treated specially beyond their implementation of the context management protocol. See the *contextlib* module for some examples.

Python's *generator*s and the *contextlib.contextmanager* decorator provide a convenient way to implement these protocols. If a generator function is decorated with the *contextlib.contextmanager* decorator, it will return a context manager implementing the necessary *__enter__()* and *__exit__()* methods, rather than the iterator produced by an undecorated generator function.

Note that there is no specific slot for any of these methods in the type structure for Python objects in the Python/C API. Extension types wanting to define these methods must provide them as a normal Python accessible method. Compared to the overhead of setting up the runtime context, the overhead of a single class dictionary lookup is negligible.

4.13 Type Annotation Types — Generic Alias, Union

The core built-in types for *type annotations* are *Generic Alias* and *Union*.

4.13.1 Generic Alias Type

`GenericAlias` objects are generally created by subscripting a class. They are most often used with container classes, such as *list* or *dict*. For example, `list[int]` is a `GenericAlias` object created by subscripting the `list` class with the argument *int*. `GenericAlias` objects are intended primarily for use with *type annotations*.

> **Note**
>
> It is generally only possible to subscript a class if the class implements the special method `__class_getitem__()`.

A `GenericAlias` object acts as a proxy for a *generic type*, implementing *parameterized generics*.

For a container class, the argument(s) supplied to a subscription of the class may indicate the type(s) of the elements an object contains. For example, `set[bytes]` can be used in type annotations to signify a *set* in which all the elements are of type *bytes*.

For a class which defines `__class_getitem__()` but is not a container, the argument(s) supplied to a subscription of the class will often indicate the return type(s) of one or more methods defined on an object. For example, *regular expressions* can be used on both the *str* data type and the *bytes* data type:

- If `x = re.search('foo', 'foo')`, `x` will be a *re.Match* object where the return values of `x.group(0)` and `x[0]` will both be of type *str*. We can represent this kind of object in type annotations with the `GenericAlias re.Match[str]`.
- If `y = re.search(b'bar', b'bar')`, (note the `b` for *bytes*), `y` will also be an instance of `re.Match`, but the return values of `y.group(0)` and `y[0]` will both be of type *bytes*. In type annotations, we would represent this variety of *re.Match* objects with `re.Match[bytes]`.

`GenericAlias` objects are instances of the class *types.GenericAlias*, which can also be used to create `GenericAlias` objects directly.

`T[X, Y, ...]`

Creates a `GenericAlias` representing a type `T` parameterized by types *X*, *Y*, and more depending on the `T` used. For example, a function expecting a *list* containing *float* elements:

```
def average(values: list[float]) -> float:
    return sum(values) / len(values)
```

Another example for *mapping* objects, using a `dict`, which is a generic type expecting two type parameters representing the key type and the value type. In this example, the function expects a `dict` with keys of type `str` and values of type `int`:

```
def send_post_request(url: str, body: dict[str, int]) -> None:
    ...
```

The builtin functions `isinstance()` and `issubclass()` do not accept `GenericAlias` types for their second argument:

```
>>> isinstance([1, 2], list[str])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

The Python runtime does not enforce *type annotations*. This extends to generic types and their type parameters. When creating a container object from a `GenericAlias`, the elements in the container are not checked against their type. For example, the following code is discouraged, but will run without errors:

```
>>> t = list[str]
>>> t([1, 2, 3])
[1, 2, 3]
```

Furthermore, parameterized generics erase type parameters during object creation:

```
>>> t = list[str]
>>> type(t)
<class 'types.GenericAlias'>

>>> l = t()
>>> type(l)
<class 'list'>
```

Calling `repr()` or `str()` on a generic shows the parameterized type:

```
>>> repr(list[int])
'list[int]'

>>> str(list[int])
'list[int]'
```

The `__getitem__()` method of generic containers will raise an exception to disallow mistakes like `dict[str][str]`:

```
>>> dict[str][str]
Traceback (most recent call last):
  ...
TypeError: dict[str] is not a generic class
```

However, such expressions are valid when *type variables* are used. The index must have as many elements as there are type variable items in the `GenericAlias` object's `__args__`.

```
>>> from typing import TypeVar
>>> Y = TypeVar('Y')
>>> dict[str, Y][int]
dict[str, int]
```

Standard Generic Classes

The following standard library classes support parameterized generics. This list is non-exhaustive.

- *tuple*
- *list*
- *dict*
- *set*
- *frozenset*
- *type*
- *asyncio.Future*
- *asyncio.Task*
- *collections.deque*
- *collections.defaultdict*
- *collections.OrderedDict*
- *collections.Counter*
- *collections.ChainMap*
- *collections.abc.Awaitable*
- *collections.abc.Coroutine*
- *collections.abc.AsyncIterable*
- *collections.abc.AsyncIterator*
- *collections.abc.AsyncGenerator*
- *collections.abc.Iterable*
- *collections.abc.Iterator*
- *collections.abc.Generator*
- *collections.abc.Reversible*
- *collections.abc.Container*
- *collections.abc.Collection*
- *collections.abc.Callable*
- *collections.abc.Set*
- *collections.abc.MutableSet*
- *collections.abc.Mapping*
- *collections.abc.MutableMapping*
- *collections.abc.Sequence*
- *collections.abc.MutableSequence*
- *collections.abc.ByteString*
- *collections.abc.MappingView*
- *collections.abc.KeysView*
- *collections.abc.ItemsView*
- *collections.abc.ValuesView*
- *contextlib.AbstractContextManager*

- *contextlib.AbstractAsyncContextManager*
- *dataclasses.Field*
- *functools.cached_property*
- *functools.partialmethod*
- *os.PathLike*
- *queue.LifoQueue*
- *queue.Queue*
- *queue.PriorityQueue*
- *queue.SimpleQueue*
- *re.Pattern*
- *re.Match*
- *shelve.BsdDbShelf*
- *shelve.DbfilenameShelf*
- *shelve.Shelf*
- *types.MappingProxyType*
- *weakref.WeakKeyDictionary*
- *weakref.WeakMethod*
- *weakref.WeakSet*
- *weakref.WeakValueDictionary*

Special Attributes of `GenericAlias` objects

All parameterized generics implement special read-only attributes.

`genericalias.__origin__`

This attribute points at the non-parameterized generic class:

```
>>> list[int].__origin__
<class 'list'>
```

`genericalias.__args__`

This attribute is a *tuple* (possibly of length 1) of generic types passed to the original `__class_getitem__()` of the generic class:

```
>>> dict[str, list[int]].__args__
(<class 'str'>, list[int])
```

`genericalias.__parameters__`

This attribute is a lazily computed tuple (possibly empty) of unique type variables found in `__args__`:

```
>>> from typing import TypeVar

>>> T = TypeVar('T')
>>> list[T].__parameters__
(~T,)
```

> **Note**
>
> A `GenericAlias` object with *`typing.ParamSpec`* parameters may not have correct `__parameters__` after substitution because *`typing.ParamSpec`* is intended primarily for static type checking.

`genericalias.`**`__unpacked__`**

A boolean that is true if the alias has been unpacked using the `*` operator (see *`TypeVarTuple`*).

Added in version 3.11.

> **See also**
>
> **PEP 484** - **Type Hints**
> Introducing Python's framework for type annotations.
>
> **PEP 585** - **Type Hinting Generics In Standard Collections**

>
> ***Generics***, ***user-defined generics*** **and** ***`typing.Generic`***
> Documentation on how to implement generic classes that can be parameterized at runtime and understood by static type-checkers.

Added in version 3.9.

4.13.2 Union Type

A union object holds the value of the `|` (bitwise or) operation on multiple *type objects*. These types are intended primarily for *type annotations*. The union type expression enables cleaner type hinting syntax compared to *`typing.Union`*.

`X | Y | ...`

Defines a union object which holds types *X*, *Y*, and so forth. `X | Y` means either X or Y. It is equivalent to `typing.Union[X, Y]`. For example, the following function expects an argument of type *`int`* or *`float`*:

```
def square(number: int | float) -> int | float:
    return number ** 2
```

> **Note**
>
> The `|` operand cannot be used at runtime to define unions where one or more members is a forward reference. For example, `int | "Foo"`, where `"Foo"` is a reference to a class not yet defined, will fail at runtime. For unions which include forward references, present the whole expression as a string, e.g. `"int | Foo"`.

`union_object == other`

Union objects can be tested for equality with other union objects. Details:

- Unions of unions are flattened:

```
(int | str) | float == int | str | float
```

- Redundant types are removed:

```
int | str | int == int | str
```

- When comparing unions, the order is ignored:

```
int | str == str | int
```

- It is compatible with *typing.Union*:

```
int | str == typing.Union[int, str]
```

- Optional types can be spelled as a union with `None`:

```
str | None == typing.Optional[str]
```

isinstance(obj, union_object)

issubclass(obj, union_object)

Calls to *isinstance()* and *issubclass()* are also supported with a union object:

```
>>> isinstance("", int | str)
True
```

However, *parameterized generics* in union objects cannot be checked:

```
>>> isinstance(1, int | list[int])  # short-circuit evaluation
True
>>> isinstance([1], int | list[int])
Traceback (most recent call last):
  ...
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

The user-exposed type for the union object can be accessed from *types.UnionType* and used for *isinstance()* checks. An object cannot be instantiated from the type:

```
>>> import types
>>> isinstance(int | str, types.UnionType)
True
>>> types.UnionType()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot create 'types.UnionType' instances
```

Note

The `__or__()` method for type objects was added to support the syntax `X | Y`. If a metaclass implements `__or__()`, the Union may override it:

```
>>> class M(type):
...     def __or__(self, other):
...         return "Hello"
...
>>> class C(metaclass=M):
...     pass
...
>>> C | int
'Hello'
>>> int | C
int | C
```

See also

PEP 604 – PEP proposing the `X | Y` syntax and the Union type.

Added in version 3.10.

4.14 Other Built-in Types

The interpreter supports several other kinds of objects. Most of these support only one or two operations.

4.14.1 Modules

The only special operation on a module is attribute access: `m.name`, where *m* is a module and *name* accesses a name defined in *m*'s symbol table. Module attributes can be assigned to. (Note that the `import` statement is not, strictly speaking, an operation on a module object; `import foo` does not require a module object named *foo* to exist, rather it requires an (external) *definition* for a module named *foo* somewhere.)

A special attribute of every module is `__dict__`. This is the dictionary containing the module's symbol table. Modifying this dictionary will actually change the module's symbol table, but direct assignment to the `__dict__` attribute is not possible (you can write `m.__dict__['a'] = 1`, which defines `m.a` to be `1`, but you can't write `m.__dict__ = {}`). Modifying `__dict__` directly is not recommended.

Modules built into the interpreter are written like this: `<module 'sys' (built-in)>`. If loaded from a file, they are written as `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

4.14.2 Classes and Class Instances

See objects and class for these.

4.14.3 Functions

Function objects are created by function definitions. The only operation on a function object is to call it: `func(argument-list)`.

There are really two flavors of function objects: built-in functions and user-defined functions. Both support the same operation (to call the function), but the implementation is different, hence the different object types.

See function for more information.

4.14.4 Methods

Methods are functions that are called using the attribute notation. There are two flavors: built-in methods (such as `append()` on lists) and class instance method. Built-in methods are described with the types that support them.

If you access a method (a function defined in a class namespace) through an instance, you get a special object: a *bound method* (also called instance method) object. When called, it will add the `self` argument to the argument list. Bound methods have two special read-only attributes: `m.__self__` is the object on which the method operates, and `m.__func__` is the function implementing the method. Calling `m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.__func__(m.__self__, arg-1, arg-2, ..., arg-n)`.

Like function objects, bound method objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`method.__func__`), setting method attributes on bound methods is disallowed. Attempting to set an attribute on a method results in an *`AttributeError`* being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object:

```
>>> class C:
...     def method(self):
...         pass
...
```

(continues on next page)

(continued from previous page)

```
>>> c = C()
>>> c.method.whoami = 'my name is method'  # can't set on the method
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'method' object has no attribute 'whoami'
>>> c.method.__func__.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

See instance-methods for more information.

4.14.5 Code Objects

Code objects are used by the implementation to represent "pseudo-compiled" executable Python code such as a function body. They differ from function objects because they don't contain a reference to their global execution environment. Code objects are returned by the built-in *compile()* function and can be extracted from function objects through their `__code__` attribute. See also the *code* module.

Accessing `__code__` raises an *auditing event* `object.__getattr__` with arguments `obj` and `"__code__"`.

A code object can be executed or evaluated by passing it (instead of a source string) to the *exec()* or *eval()* built-in functions.

See types for more information.

4.14.6 Type Objects

Type objects represent the various object types. An object's type is accessed by the built-in function *type()*. There are no special operations on types. The standard module *types* defines names for all standard built-in types.

Types are written like this: `<class 'int'>`.

4.14.7 The Null Object

This object is returned by functions that don't explicitly return a value. It supports no special operations. There is exactly one null object, named `None` (a built-in name). `type(None)()` produces the same singleton.

It is written as `None`.

4.14.8 The Ellipsis Object

This object is commonly used by slicing (see slicings). It supports no special operations. There is exactly one ellipsis object, named *Ellipsis* (a built-in name). `type(Ellipsis)()` produces the *Ellipsis* singleton.

It is written as `Ellipsis` or `...`.

4.14.9 The NotImplemented Object

This object is returned from comparisons and binary operations when they are asked to operate on types they don't support. See comparisons for more information. There is exactly one *NotImplemented* object. `type(NotImplemented)()` produces the singleton instance.

It is written as `NotImplemented`.

4.14.10 Internal Objects

See types for this information. It describes stack frame objects, traceback objects, and slice objects.

4.15 Special Attributes

The implementation adds a few special read-only attributes to several object types, where they are relevant. Some of these are not reported by the *dir()* built-in function.

`definition.`**`__name__`**

The name of the class, function, method, descriptor, or generator instance.

`definition.`**`__qualname__`**

The *qualified name* of the class, function, method, descriptor, or generator instance.

Added in version 3.3.

`definition.`**`__module__`**

The name of the module in which a class or function was defined.

`definition.`**`__doc__`**

The documentation string of a class or function, or `None` if undefined.

`definition.`**`__type_params__`**

The type parameters of generic classes, functions, and *type aliases*. For classes and functions that are not generic, this will be an empty tuple.

Added in version 3.12.

4.16 Integer string conversion length limitation

CPython has a global limit for converting between *int* and *str* to mitigate denial of service attacks. This limit *only* applies to decimal or other non-power-of-two number bases. Hexadecimal, octal, and binary conversions are unlimited. The limit can be configured.

The *int* type in CPython is an arbitrary length number stored in binary form (commonly known as a "bignum"). There exists no algorithm that can convert a string to a binary integer or a binary integer to a string in linear time, *unless* the base is a power of 2. Even the best known algorithms for base 10 have sub-quadratic complexity. Converting a large value such as `int('1' * 500_000)` can take over a second on a fast CPU.

Limiting conversion size offers a practical way to avoid **CVE 2020-10735**.

The limit is applied to the number of digit characters in the input or output string when a non-linear conversion algorithm would be involved. Underscores and the sign are not counted towards the limit.

When an operation would exceed the limit, a *ValueError* is raised:

```
>>> import sys
>>> sys.set_int_max_str_digits(4300)  # Illustrative, this is the default.
>>> _ = int('2' * 5432)
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer string conversion: value␣
↪has 5432 digits; use sys.set_int_max_str_digits() to increase the limit
>>> i = int('2' * 4300)
>>> len(str(i))
4300
>>> i_squared = i*i
>>> len(str(i_squared))
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer string conversion; use sys.
↪set_int_max_str_digits() to increase the limit
>>> len(hex(i_squared))
```

(continues on next page)

(continued from previous page)

```
7144
>>> assert int(hex(i_squared), base=16) == i*i  # Hexadecimal is unlimited.
```

The default limit is 4300 digits as provided in *sys.int_info.default_max_str_digits*. The lowest limit that can be configured is 640 digits as provided in *sys.int_info.str_digits_check_threshold*.

Verification:

```
>>> import sys
>>> assert sys.int_info.default_max_str_digits == 4300, sys.int_info
>>> assert sys.int_info.str_digits_check_threshold == 640, sys.int_info
>>> msg = int('578966293710682886880994035146873798396722250538762761564'
...           '9252925514383915483333812743580549779436104706260696366600'
...           '571186405732').to_bytes(53, 'big')
...
```

Added in version 3.11.

4.16.1 Affected APIs

The limitation only applies to potentially slow conversions between *int* and *str* or *bytes*:

- `int(string)` with default base 10.
- `int(string, base)` for all bases that are not a power of 2.
- `str(integer)`.
- `repr(integer)`.
- any other string conversion to base 10, for example `f"{integer}"`, `"{}".format(integer)`, or `b"%d" % integer`.

The limitations do not apply to functions with a linear algorithm:

- `int(string, base)` with base 2, 4, 8, 16, or 32.
- *int.from_bytes()* and *int.to_bytes()*.
- *hex()*, *oct()*, *bin()*.
- *Format Specification Mini-Language* for hex, octal, and binary numbers.
- *str* to *float*.
- *str* to *decimal.Decimal*.

4.16.2 Configuring the limit

Before Python starts up you can use an environment variable or an interpreter command line flag to configure the limit:

- `PYTHONINTMAXSTRDIGITS`, e.g. `PYTHONINTMAXSTRDIGITS=640 python3` to set the limit to 640 or `PYTHONINTMAXSTRDIGITS=0 python3` to disable the limitation.
- `-X int_max_str_digits`, e.g. `python3 -X int_max_str_digits=640`
- *sys.flags.int_max_str_digits* contains the value of `PYTHONINTMAXSTRDIGITS` or `-X int_max_str_digits`. If both the env var and the `-X` option are set, the `-X` option takes precedence. A value of *-1* indicates that both were unset, thus a value of *sys.int_info.default_max_str_digits* was used during initialization.

From code, you can inspect the current limit and set a new one using these *sys* APIs:

- *sys.get_int_max_str_digits()* and *sys.set_int_max_str_digits()* are a getter and setter for the interpreter-wide limit. Subinterpreters have their own limit.

Information about the default and minimum can be found in *sys.int_info*:

- *sys.int_info.default_max_str_digits* is the compiled-in default limit.
- *sys.int_info.str_digits_check_threshold* is the lowest accepted value for the limit (other than 0 which disables it).

Added in version 3.11.

Caution

Setting a low limit *can* lead to problems. While rare, code exists that contains integer constants in decimal in their source that exceed the minimum threshold. A consequence of setting the limit is that Python source code containing decimal integer literals longer than the limit will encounter an error during parsing, usually at startup time or import time or even at installation time - anytime an up to date `.pyc` does not already exist for the code. A workaround for source that contains such large constants is to convert them to `0x` hexadecimal form as it has no limit.

Test your application thoroughly if you use a low limit. Ensure your tests run with the limit set early via the environment or flag so that it applies during startup and even during any installation step that may invoke Python to precompile `.py` sources to `.pyc` files.

4.16.3 Recommended configuration

The default *sys.int_info.default_max_str_digits* is expected to be reasonable for most applications. If your application requires a different limit, set it from your main entry point using Python version agnostic code as these APIs were added in security patch releases in versions before 3.12.

Example:

```
>>> import sys
>>> if hasattr(sys, "set_int_max_str_digits"):
...     upper_bound = 68000
...     lower_bound = 4004
...     current_limit = sys.get_int_max_str_digits()
...     if current_limit == 0 or current_limit > upper_bound:
...         sys.set_int_max_str_digits(upper_bound)
...     elif current_limit < lower_bound:
...         sys.set_int_max_str_digits(lower_bound)
```

If you need to disable it entirely, set it to `0`.

CHAPTER

FIVE

BUILT-IN EXCEPTIONS

In Python, all exceptions must be instances of a class that derives from *BaseException*. In a `try` statement with an `except` clause that mentions a particular class, that clause also handles any exception classes derived from that class (but not exception classes from which *it* is derived). Two exception classes that are not related via subclassing are never equivalent, even if they have the same name.

The built-in exceptions listed in this chapter can be generated by the interpreter or built-in functions. Except where mentioned, they have an "associated value" indicating the detailed cause of the error. This may be a string or a tuple of several items of information (e.g., an error code and a string explaining the code). The associated value is usually passed as arguments to the exception class's constructor.

User code can raise built-in exceptions. This can be used to test an exception handler or to report an error condition "just like" the situation in which the interpreter raises the same exception; but beware that there is nothing to prevent user code from raising an inappropriate error.

The built-in exception classes can be subclassed to define new exceptions; programmers are encouraged to derive new exceptions from the *Exception* class or one of its subclasses, and not from *BaseException*. More information on defining exceptions is available in the Python Tutorial under tut-userexceptions.

5.1 Exception context

Three attributes on exception objects provide information about the context in which the exception was raised:

`BaseException.`**`__context__`**

`BaseException.`**`__cause__`**

`BaseException.`**`__suppress_context__`**

When raising a new exception while another exception is already being handled, the new exception's `__context__` attribute is automatically set to the handled exception. An exception may be handled when an `except` or `finally` clause, or a `with` statement, is used.

This implicit exception context can be supplemented with an explicit cause by using `from` with `raise`:

```
raise new_exc from original_exc
```

The expression following `from` must be an exception or `None`. It will be set as `__cause__` on the raised exception. Setting `__cause__` also implicitly sets the `__suppress_context__` attribute to `True`, so that using `raise new_exc from None` effectively replaces the old exception with the new one for display purposes (e.g. converting *KeyError* to *AttributeError*), while leaving the old exception available in `__context__` for introspection when debugging.

The default traceback display code shows these chained exceptions in addition to the traceback for the exception itself. An explicitly chained exception in `__cause__` is always shown when present. An implicitly chained exception in `__context__` is shown only if `__cause__` is *None* and `__suppress_context__` is false.

In either case, the exception itself is always shown after any chained exceptions so that the final line of the traceback always shows the last exception that was raised.

5.2 Inheriting from built-in exceptions

User code can create subclasses that inherit from an exception type. It's recommended to only subclass one exception type at a time to avoid any possible conflicts between how the bases handle the `args` attribute, as well as due to possible memory layout incompatibilities.

CPython implementation detail: Most built-in exceptions are implemented in C for efficiency, see: Objects/exceptions.c. Some have custom memory layouts which makes it impossible to create a subclass that inherits from multiple exception types. The memory layout of a type is an implementation detail and might change between Python versions, leading to new conflicts in the future. Therefore, it's recommended to avoid subclassing multiple exception types altogether.

5.3 Base classes

The following exceptions are used mostly as base classes for other exceptions.

exception BaseException

The base class for all built-in exceptions. It is not meant to be directly inherited by user-defined classes (for that, use *Exception*). If *str()* is called on an instance of this class, the representation of the argument(s) to the instance are returned, or the empty string when there were no arguments.

args

The tuple of arguments given to the exception constructor. Some built-in exceptions (like *OSError*) expect a certain number of arguments and assign a special meaning to the elements of this tuple, while others are usually called only with a single string giving an error message.

with_traceback(*tb*)

This method sets *tb* as the new traceback for the exception and returns the exception object. It was more commonly used before the exception chaining features of **PEP 3134** became available. The following example shows how we can convert an instance of `SomeException` into an instance of `OtherException` while preserving the traceback. Once raised, the current frame is pushed onto the traceback of the `OtherException`, as would have happened to the traceback of the original `SomeException` had we allowed it to propagate to the caller.

```
try:
    ...
except SomeException:
    tb = sys.exception().__traceback__
    raise OtherException(...).with_traceback(tb)
```

__traceback__

A writable field that holds the traceback object associated with this exception. See also: raise.

add_note(*note*)

Add the string `note` to the exception's notes which appear in the standard traceback after the exception string. A *TypeError* is raised if `note` is not a string.

Added in version 3.11.

__notes__

A list of the notes of this exception, which were added with *add_note()*. This attribute is created when *add_note()* is called.

Added in version 3.11.

exception Exception

All built-in, non-system-exiting exceptions are derived from this class. All user-defined exceptions should also be derived from this class.

exception ArithmeticError

The base class for those built-in exceptions that are raised for various arithmetic errors: *OverflowError*, *ZeroDivisionError*, *FloatingPointError*.

exception BufferError

Raised when a buffer related operation cannot be performed.

exception LookupError

The base class for the exceptions that are raised when a key or index used on a mapping or sequence is invalid: *IndexError*, *KeyError*. This can be raised directly by *codecs.lookup()*.

5.4 Concrete exceptions

The following exceptions are the exceptions that are usually raised.

exception AssertionError

Raised when an `assert` statement fails.

exception AttributeError

Raised when an attribute reference (see attribute-references) or assignment fails. (When an object does not support attribute references or attribute assignments at all, *TypeError* is raised.)

The `name` and `obj` attributes can be set using keyword-only arguments to the constructor. When set they represent the name of the attribute that was attempted to be accessed and the object that was accessed for said attribute, respectively.

Changed in version 3.10: Added the `name` and `obj` attributes.

exception EOFError

Raised when the *input()* function hits an end-of-file condition (EOF) without reading any data. (N.B.: the `io.IOBase.read()` and *io.IOBase.readline()* methods return an empty string when they hit EOF.)

exception FloatingPointError

Not currently used.

exception GeneratorExit

Raised when a *generator* or *coroutine* is closed; see `generator.close()` and `coroutine.close()`. It directly inherits from *BaseException* instead of *Exception* since it is technically not an error.

exception ImportError

Raised when the `import` statement has troubles trying to load a module. Also raised when the "from list" in `from ... import` has a name that cannot be found.

The optional *name* and *path* keyword-only arguments set the corresponding attributes:

name

The name of the module that was attempted to be imported.

path

The path to any file which triggered the exception.

Changed in version 3.3: Added the *name* and *path* attributes.

exception ModuleNotFoundError

A subclass of *ImportError* which is raised by `import` when a module could not be located. It is also raised when `None` is found in *sys.modules*.

Added in version 3.6.

exception IndexError

Raised when a sequence subscript is out of range. (Slice indices are silently truncated to fall in the allowed range; if an index is not an integer, *TypeError* is raised.)

exception KeyError

Raised when a mapping (dictionary) key is not found in the set of existing keys.

exception KeyboardInterrupt

Raised when the user hits the interrupt key (normally `Control-C` or `Delete`). During execution, a check for interrupts is made regularly. The exception inherits from *BaseException* so as to not be accidentally caught by code that catches *Exception* and thus prevent the interpreter from exiting.

> **Note**
>
> Catching a *KeyboardInterrupt* requires special consideration. Because it can be raised at unpredictable points, it may, in some circumstances, leave the running program in an inconsistent state. It is generally best to allow *KeyboardInterrupt* to end the program as quickly as possible or avoid raising it entirely. (See *Note on Signal Handlers and Exceptions*.)

exception MemoryError

Raised when an operation runs out of memory but the situation may still be rescued (by deleting some objects). The associated value is a string indicating what kind of (internal) operation ran out of memory. Note that because of the underlying memory management architecture (C's `malloc()` function), the interpreter may not always be able to completely recover from this situation; it nevertheless raises an exception so that a stack traceback can be printed, in case a run-away program was the cause.

exception NameError

Raised when a local or global name is not found. This applies only to unqualified names. The associated value is an error message that includes the name that could not be found.

The `name` attribute can be set using a keyword-only argument to the constructor. When set it represent the name of the variable that was attempted to be accessed.

Changed in version 3.10: Added the `name` attribute.

exception NotImplementedError

This exception is derived from *RuntimeError*. In user defined base classes, abstract methods should raise this exception when they require derived classes to override the method, or while the class is being developed to indicate that the real implementation still needs to be added.

> **Note**
>
> It should not be used to indicate that an operator or method is not meant to be supported at all – in that case either leave the operator / method undefined or, if a subclass, set it to *None*.

> **Caution**
>
> `NotImplementedError` and `NotImplemented` are not interchangeable. This exception should only be used as described above; see *NotImplemented* for details on correct usage of the built-in constant.

exception OSError(*[arg]*)

exception OSError(*errno*, *strerror*[, *filename*[, *winerror*[, *filename2*]]])

This exception is raised when a system function returns a system-related error, including I/O failures such as "file not found" or "disk full" (not for illegal argument types or other incidental errors).

The second form of the constructor sets the corresponding attributes, described below. The attributes default to *None* if not specified. For backwards compatibility, if three arguments are passed, the *args* attribute contains only a 2-tuple of the first two constructor arguments.

The constructor often actually returns a subclass of *OSError*, as described in *OS exceptions* below. The particular subclass depends on the final *errno* value. This behaviour only occurs when constructing *OSError* directly or via an alias, and is not inherited when subclassing.

errno

A numeric error code from the C variable `errno`.

winerror

Under Windows, this gives you the native Windows error code. The *errno* attribute is then an approximate translation, in POSIX terms, of that native error code.

Under Windows, if the *winerror* constructor argument is an integer, the *errno* attribute is determined from the Windows error code, and the *errno* argument is ignored. On other platforms, the *winerror* argument is ignored, and the *winerror* attribute does not exist.

strerror

The corresponding error message, as provided by the operating system. It is formatted by the C functions `perror()` under POSIX, and `FormatMessage()` under Windows.

filename

filename2

For exceptions that involve a file system path (such as *open()* or *os.unlink()*), *filename* is the file name passed to the function. For functions that involve two file system paths (such as *os.rename()*), *filename2* corresponds to the second file name passed to the function.

Changed in version 3.3: *EnvironmentError*, *IOError*, *WindowsError*, *socket.error*, *select.error* and `mmap.error` have been merged into *OSError*, and the constructor may return a subclass.

Changed in version 3.4: The *filename* attribute is now the original file name passed to the function, instead of the name encoded to or decoded from the *filesystem encoding and error handler*. Also, the *filename2* constructor argument and attribute was added.

exception OverflowError

Raised when the result of an arithmetic operation is too large to be represented. This cannot occur for integers (which would rather raise *MemoryError* than give up). However, for historical reasons, OverflowError is sometimes raised for integers that are outside a required range. Because of the lack of standardization of floating-point exception handling in C, most floating-point operations are not checked.

exception PythonFinalizationError

This exception is derived from *RuntimeError*. It is raised when an operation is blocked during interpreter shutdown also known as *Python finalization*.

Examples of operations which can be blocked with a *PythonFinalizationError* during the Python finalization:

- Creating a new Python thread.
- *os.fork()*.

See also the *sys.is_finalizing()* function.

Added in version 3.13: Previously, a plain *RuntimeError* was raised.

exception RecursionError

This exception is derived from *RuntimeError*. It is raised when the interpreter detects that the maximum recursion depth (see *sys.getrecursionlimit()*) is exceeded.

Added in version 3.5: Previously, a plain *RuntimeError* was raised.

exception ReferenceError

This exception is raised when a weak reference proxy, created by the *weakref.proxy()* function, is used to access an attribute of the referent after it has been garbage collected. For more information on weak references, see the *weakref* module.

exception RuntimeError

Raised when an error is detected that doesn't fall in any of the other categories. The associated value is a string indicating what precisely went wrong.

exception StopIteration

Raised by built-in function `next()` and an *iterator*'s `__next__()` method to signal that there are no further items produced by the iterator.

value

The exception object has a single attribute `value`, which is given as an argument when constructing the exception, and defaults to `None`.

When a *generator* or *coroutine* function returns, a new `StopIteration` instance is raised, and the value returned by the function is used as the `value` parameter to the constructor of the exception.

If a generator code directly or indirectly raises `StopIteration`, it is converted into a `RuntimeError` (retaining the `StopIteration` as the new exception's cause).

Changed in version 3.3: Added `value` attribute and the ability for generator functions to use it to return a value.

Changed in version 3.5: Introduced the RuntimeError transformation via `from __future__ import generator_stop`, see **PEP 479**.

Changed in version 3.7: Enable **PEP 479** for all code by default: a `StopIteration` error raised in a generator is transformed into a `RuntimeError`.

exception StopAsyncIteration

Must be raised by `__anext__()` method of an *asynchronous iterator* object to stop the iteration.

Added in version 3.5.

exception SyntaxError(*message*, *details*)

Raised when the parser encounters a syntax error. This may occur in an `import` statement, in a call to the built-in functions `compile()`, `exec()`, or `eval()`, or when reading the initial script or standard input (also interactively).

The `str()` of the exception instance returns only the error message. Details is a tuple whose members are also available as separate attributes.

filename

The name of the file the syntax error occurred in.

lineno

Which line number in the file the error occurred in. This is 1-indexed: the first line in the file has a `lineno` of 1.

offset

The column in the line where the error occurred. This is 1-indexed: the first character in the line has an `offset` of 1.

text

The source code text involved in the error.

end_lineno

Which line number in the file the error occurred ends in. This is 1-indexed: the first line in the file has a `lineno` of 1.

end_offset

The column in the end line where the error occurred finishes. This is 1-indexed: the first character in the line has an `offset` of 1.

For errors in f-string fields, the message is prefixed by "f-string: " and the offsets are offsets in a text constructed from the replacement expression. For example, compiling f'Bad {a b} field' results in this args attribute: ('f-string: …', (", 1, 2, '(a b)n', 1, 5)).

Changed in version 3.10: Added the *end_lineno* and *end_offset* attributes.

exception IndentationError

Base class for syntax errors related to incorrect indentation. This is a subclass of *SyntaxError*.

exception TabError

Raised when indentation contains an inconsistent use of tabs and spaces. This is a subclass of *IndentationError*.

exception SystemError

Raised when the interpreter finds an internal error, but the situation does not look so serious to cause it to abandon all hope. The associated value is a string indicating what went wrong (in low-level terms). In *CPython*, this could be raised by incorrectly using Python's C API, such as returning a `NULL` value without an exception set.

If you're confident that this exception wasn't your fault, or the fault of a package you're using, you should report this to the author or maintainer of your Python interpreter. Be sure to report the version of the Python interpreter (`sys.version`; it is also printed at the start of an interactive Python session), the exact error message (the exception's associated value) and if possible the source of the program that triggered the error.

exception SystemExit

This exception is raised by the *sys.exit()* function. It inherits from *BaseException* instead of *Exception* so that it is not accidentally caught by code that catches *Exception*. This allows the exception to properly propagate up and cause the interpreter to exit. When it is not handled, the Python interpreter exits; no stack traceback is printed. The constructor accepts the same optional argument passed to *sys.exit()*. If the value is an integer, it specifies the system exit status (passed to C's `exit()` function); if it is `None`, the exit status is zero; if it has another type (such as a string), the object's value is printed and the exit status is one.

A call to *sys.exit()* is translated into an exception so that clean-up handlers (`finally` clauses of `try` statements) can be executed, and so that a debugger can execute a script without running the risk of losing control. The *os._exit()* function can be used if it is absolutely positively necessary to exit immediately (for example, in the child process after a call to *os.fork()*).

code

The exit status or error message that is passed to the constructor. (Defaults to `None`.)

exception TypeError

Raised when an operation or function is applied to an object of inappropriate type. The associated value is a string giving details about the type mismatch.

This exception may be raised by user code to indicate that an attempted operation on an object is not supported, and is not meant to be. If an object is meant to support a given operation but has not yet provided an implementation, *NotImplementedError* is the proper exception to raise.

Passing arguments of the wrong type (e.g. passing a *list* when an *int* is expected) should result in a *TypeError*, but passing arguments with the wrong value (e.g. a number outside expected boundaries) should result in a *ValueError*.

exception UnboundLocalError

Raised when a reference is made to a local variable in a function or method, but no value has been bound to that variable. This is a subclass of *NameError*.

exception UnicodeError

Raised when a Unicode-related encoding or decoding error occurs. It is a subclass of *ValueError*.

UnicodeError has attributes that describe the encoding or decoding error. For example, `err.object[err.start:err.end]` gives the particular invalid input that the codec failed on.

encoding

The name of the encoding that raised the error.

reason

A string describing the specific codec error.

object

The object the codec was attempting to encode or decode.

start

The first index of invalid data in *object*.

end

The index after the last invalid data in *object*.

exception UnicodeEncodeError

Raised when a Unicode-related error occurs during encoding. It is a subclass of *UnicodeError*.

exception UnicodeDecodeError

Raised when a Unicode-related error occurs during decoding. It is a subclass of *UnicodeError*.

exception UnicodeTranslateError

Raised when a Unicode-related error occurs during translating. It is a subclass of *UnicodeError*.

exception ValueError

Raised when an operation or function receives an argument that has the right type but an inappropriate value, and the situation is not described by a more precise exception such as *IndexError*.

exception ZeroDivisionError

Raised when the second argument of a division or modulo operation is zero. The associated value is a string indicating the type of the operands and the operation.

The following exceptions are kept for compatibility with previous versions; starting from Python 3.3, they are aliases of *OSError*.

exception EnvironmentError

exception IOError

exception WindowsError

Only available on Windows.

5.4.1 OS exceptions

The following exceptions are subclasses of *OSError*, they get raised depending on the system error code.

exception BlockingIOError

Raised when an operation would block on an object (e.g. socket) set for non-blocking operation. Corresponds to `errno` *EAGAIN*, *EALREADY*, *EWOULDBLOCK* and *EINPROGRESS*.

In addition to those of *OSError*, *BlockingIOError* can have one more attribute:

characters_written

An integer containing the number of characters written to the stream before it blocked. This attribute is available when using the buffered I/O classes from the *io* module.

exception ChildProcessError

Raised when an operation on a child process failed. Corresponds to `errno` *ECHILD*.

exception ConnectionError

A base class for connection-related issues.

Subclasses are *BrokenPipeError*, *ConnectionAbortedError*, *ConnectionRefusedError* and *ConnectionResetError*.

exception BrokenPipeError

A subclass of *ConnectionError*, raised when trying to write on a pipe while the other end has been closed, or trying to write on a socket which has been shutdown for writing. Corresponds to `errno` *EPIPE* and *ESHUTDOWN*.

exception ConnectionAbortedError

A subclass of *ConnectionError*, raised when a connection attempt is aborted by the peer. Corresponds to errno *ECONNABORTED*.

exception ConnectionRefusedError

A subclass of *ConnectionError*, raised when a connection attempt is refused by the peer. Corresponds to errno *ECONNREFUSED*.

exception ConnectionResetError

A subclass of *ConnectionError*, raised when a connection is reset by the peer. Corresponds to errno *ECONNRESET*.

exception FileExistsError

Raised when trying to create a file or directory which already exists. Corresponds to errno *EEXIST*.

exception FileNotFoundError

Raised when a file or directory is requested but doesn't exist. Corresponds to errno *ENOENT*.

exception InterruptedError

Raised when a system call is interrupted by an incoming signal. Corresponds to errno *EINTR*.

Changed in version 3.5: Python now retries system calls when a syscall is interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

exception IsADirectoryError

Raised when a file operation (such as *os.remove()*) is requested on a directory. Corresponds to errno *EISDIR*.

exception NotADirectoryError

Raised when a directory operation (such as *os.listdir()*) is requested on something which is not a directory. On most POSIX platforms, it may also be raised if an operation attempts to open or traverse a non-directory file as if it were a directory. Corresponds to errno *ENOTDIR*.

exception PermissionError

Raised when trying to run an operation without the adequate access rights - for example filesystem permissions. Corresponds to errno *EACCES*, *EPERM*, and *ENOTCAPABLE*.

Changed in version 3.11.1: WASI's *ENOTCAPABLE* is now mapped to *PermissionError*.

exception ProcessLookupError

Raised when a given process doesn't exist. Corresponds to errno *ESRCH*.

exception TimeoutError

Raised when a system function timed out at the system level. Corresponds to errno *ETIMEDOUT*.

Added in version 3.3: All the above *OSError* subclasses were added.

See also

PEP 3151 - Reworking the OS and IO exception hierarchy

5.5 Warnings

The following exceptions are used as warning categories; see the *Warning Categories* documentation for more details.

exception Warning

Base class for warning categories.

exception UserWarning

Base class for warnings generated by user code.

exception DeprecationWarning

Base class for warnings about deprecated features when those warnings are intended for other Python developers.

Ignored by the default warning filters, except in the `__main__` module (**PEP 565**). Enabling the *Python Development Mode* shows this warning.

The deprecation policy is described in **PEP 387**.

exception PendingDeprecationWarning

Base class for warnings about features which are obsolete and expected to be deprecated in the future, but are not deprecated at the moment.

This class is rarely used as emitting a warning about a possible upcoming deprecation is unusual, and `DeprecationWarning` is preferred for already active deprecations.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

The deprecation policy is described in **PEP 387**.

exception SyntaxWarning

Base class for warnings about dubious syntax.

exception RuntimeWarning

Base class for warnings about dubious runtime behavior.

exception FutureWarning

Base class for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.

exception ImportWarning

Base class for warnings about probable mistakes in module imports.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

exception UnicodeWarning

Base class for warnings related to Unicode.

exception EncodingWarning

Base class for warnings related to encodings.

See *Opt-in EncodingWarning* for details.

Added in version 3.10.

exception BytesWarning

Base class for warnings related to `bytes` and `bytearray`.

exception ResourceWarning

Base class for warnings related to resource usage.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

Added in version 3.2.

5.6 Exception groups

The following are used when it is necessary to raise multiple unrelated exceptions. They are part of the exception hierarchy so they can be handled with `except` like all other exceptions. In addition, they are recognised by `except*`, which matches their subgroups based on the types of the contained exceptions.

exception ExceptionGroup(*msg*, *excs*)

exception BaseExceptionGroup(*msg*, *excs*)

Both of these exception types wrap the exceptions in the sequence `excs`. The `msg` parameter must be a string. The difference between the two classes is that *BaseExceptionGroup* extends *BaseException* and it can wrap any exception, while *ExceptionGroup* extends *Exception* and it can only wrap subclasses of *Exception*. This design is so that `except Exception` catches an *ExceptionGroup* but not *BaseExceptionGroup*.

The *BaseExceptionGroup* constructor returns an *ExceptionGroup* rather than a *BaseExceptionGroup* if all contained exceptions are *Exception* instances, so it can be used to make the selection automatic. The *ExceptionGroup* constructor, on the other hand, raises a *TypeError* if any contained exception is not an *Exception* subclass.

message

The `msg` argument to the constructor. This is a read-only attribute.

exceptions

A tuple of the exceptions in the `excs` sequence given to the constructor. This is a read-only attribute.

subgroup(*condition*)

Returns an exception group that contains only the exceptions from the current group that match *condition*, or `None` if the result is empty.

The condition can be an exception type or tuple of exception types, in which case each exception is checked for a match using the same check that is used in an `except` clause. The condition can also be a callable (other than a type object) that accepts an exception as its single argument and returns true for the exceptions that should be in the subgroup.

The nesting structure of the current exception is preserved in the result, as are the values of its *message*, *__traceback__*, *__cause__*, *__context__* and *__notes__* fields. Empty nested groups are omitted from the result.

The condition is checked for all exceptions in the nested exception group, including the top-level and any nested exception groups. If the condition is true for such an exception group, it is included in the result in full.

Added in version 3.13: `condition` can be any callable which is not a type object.

split(*condition*)

Like *subgroup()*, but returns the pair `(match, rest)` where `match` is `subgroup(condition)` and `rest` is the remaining non-matching part.

derive(*excs*)

Returns an exception group with the same *message*, but which wraps the exceptions in `excs`.

This method is used by *subgroup()* and *split()*, which are used in various contexts to break up an exception group. A subclass needs to override it in order to make *subgroup()* and *split()* return instances of the subclass rather than *ExceptionGroup*.

subgroup() and *split()* copy the *__traceback__*, *__cause__*, *__context__* and *__notes__* fields from the original exception group to the one returned by *derive()*, so these fields do not need to be updated by *derive()*.

```
>>> class MyGroup(ExceptionGroup):
...     def derive(self, excs):
...         return MyGroup(self.message, excs)
...
>>> e = MyGroup("eg", [ValueError(1), TypeError(2)])
>>> e.add_note("a note")
>>> e.__context__ = Exception("context")
>>> e.__cause__ = Exception("cause")
```

(continues on next page)

(continued from previous page)

```
>>> try:
...     raise e
... except Exception as e:
...     exc = e
...
>>> match, rest = exc.split(ValueError)
>>> exc, exc.__context__, exc.__cause__, exc.__notes__
(MyGroup('eg', [ValueError(1), TypeError(2)]), Exception('context'),␣
↪Exception('cause'), ['a note'])
>>> match, match.__context__, match.__cause__, match.__notes__
(MyGroup('eg', [ValueError(1)]), Exception('context'), Exception('cause'),␣
↪['a note'])
>>> rest, rest.__context__, rest.__cause__, rest.__notes__
(MyGroup('eg', [TypeError(2)]), Exception('context'), Exception('cause'), [
↪'a note'])
>>> exc.__traceback__ is match.__traceback__ is rest.__traceback__
True
```

Note that *BaseExceptionGroup* defines `__new__()`, so subclasses that need a different constructor signature need to override that rather than `__init__()`. For example, the following defines an exception group subclass which accepts an exit_code and and constructs the group's message from it.

```
class Errors(ExceptionGroup):
   def __new__(cls, errors, exit_code):
      self = super().__new__(Errors, f"exit code: {exit_code}", errors)
      self.exit_code = exit_code
      return self

   def derive(self, excs):
      return Errors(excs, self.exit_code)
```

Like *ExceptionGroup*, any subclass of *BaseExceptionGroup* which is also a subclass of *Exception* can only wrap instances of *Exception*.

Added in version 3.11.

5.7 Exception hierarchy

The class hierarchy for built-in exceptions is:

```
BaseException
 ├── BaseExceptionGroup
 ├── GeneratorExit
 ├── KeyboardInterrupt
 ├── SystemExit
 └── Exception
      ├── ArithmeticError
      │    ├── FloatingPointError
      │    ├── OverflowError
      │    └── ZeroDivisionError
      ├── AssertionError
      ├── AttributeError
      ├── BufferError
      ├── EOFError

CHAPTER

SIX

TEXT PROCESSING SERVICES

The modules described in this chapter provide a wide range of string manipulation operations and other text processing services.

The `codecs` module described under *Binary Data Services* is also highly relevant to text processing. In addition, see the documentation for Python's built-in string type in *Text Sequence Type — str*.

6.1 `string` — Common string operations

Source code: Lib/string.py

See also

Text Sequence Type — str

String Methods

6.1.1 String constants

The constants defined in this module are:

`string.`**`ascii_letters`**

The concatenation of the `ascii_lowercase` and `ascii_uppercase` constants described below. This value is not locale-dependent.

`string.`**`ascii_lowercase`**

The lowercase letters `'abcdefghijklmnopqrstuvwxyz'`. This value is not locale-dependent and will not change.

`string.`**`ascii_uppercase`**

The uppercase letters `'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. This value is not locale-dependent and will not change.

`string.`**`digits`**

The string `'0123456789'`.

`string.`**`hexdigits`**

The string `'0123456789abcdefABCDEF'`.

`string.`**`octdigits`**

The string `'01234567'`.

`string.`**`punctuation`**

String of ASCII characters which are considered punctuation characters in the `C` locale: `!"#$%&'()*+,-./:;<=>?@[\]^_`{|}~`.

string.**printable**

String of ASCII characters which are considered printable by Python. This is a combination of *digits*, *ascii_letters*, *punctuation*, and *whitespace*.

> **Note**
>
> By design, *string.printable.isprintable()* returns *False*. In particular, string.printable is not printable in the POSIX sense (see *LC_CTYPE*).

string.**whitespace**

A string containing all ASCII characters that are considered whitespace. This includes the characters space, tab, linefeed, return, formfeed, and vertical tab.

6.1.2 Custom String Formatting

The built-in string class provides the ability to do complex variable substitutions and value formatting via the *format()* method described in **PEP 3101**. The *Formatter* class in the *string* module allows you to create and customize your own string formatting behaviors using the same implementation as the built-in *format()* method.

class string.**Formatter**

The *Formatter* class has the following public methods:

format(*format_string*, /, **args*, ***kwargs*)

The primary API method. It takes a format string and an arbitrary set of positional and keyword arguments. It is just a wrapper that calls *vformat()*.

Changed in version 3.7: A format string argument is now *positional-only*.

vformat(*format_string*, *args*, *kwargs*)

This function does the actual work of formatting. It is exposed as a separate function for cases where you want to pass in a predefined dictionary of arguments, rather than unpacking and repacking the dictionary as individual arguments using the `*args` and `**kwargs` syntax. *vformat()* does the work of breaking up the format string into character data and replacement fields. It calls the various methods described below.

In addition, the *Formatter* defines a number of methods that are intended to be replaced by subclasses:

parse(*format_string*)

Loop over the format_string and return an iterable of tuples (*literal_text*, *field_name*, *format_spec*, *conversion*). This is used by *vformat()* to break the string into either literal text, or replacement fields.

The values in the tuple conceptually represent a span of literal text followed by a single replacement field. If there is no literal text (which can happen if two replacement fields occur consecutively), then *literal_text* will be a zero-length string. If there is no replacement field, then the values of *field_name*, *format_spec* and *conversion* will be `None`.

get_field(*field_name*, *args*, *kwargs*)

Given *field_name* as returned by *parse()* (see above), convert it to an object to be formatted. Returns a tuple (obj, used_key). The default version takes strings of the form defined in **PEP 3101**, such as "0[name]" or "label.title". *args* and *kwargs* are as passed in to *vformat()*. The return value *used_key* has the same meaning as the *key* parameter to *get_value()*.

get_value(*key*, *args*, *kwargs*)

Retrieve a given field value. The *key* argument will be either an integer or a string. If it is an integer, it represents the index of the positional argument in *args*; if it is a string, then it represents a named argument in *kwargs*.

The *args* parameter is set to the list of positional arguments to *vformat()*, and the *kwargs* parameter is set to the dictionary of keyword arguments.

For compound field names, these functions are only called for the first component of the field name; subsequent components are handled through normal attribute and indexing operations.

So for example, the field expression '0.name' would cause *get_value()* to be called with a *key* argument of 0. The `name` attribute will be looked up after *get_value()* returns by calling the built-in *getattr()* function.

If the index or keyword refers to an item that does not exist, then an *IndexError* or *KeyError* should be raised.

check_unused_args(*used_args*, *args*, *kwargs*)

Implement checking for unused arguments if desired. The arguments to this function is the set of all argument keys that were actually referred to in the format string (integers for positional arguments, and strings for named arguments), and a reference to the *args* and *kwargs* that was passed to vformat. The set of unused args can be calculated from these parameters. *check_unused_args()* is assumed to raise an exception if the check fails.

format_field(*value*, *format_spec*)

format_field() simply calls the global *format()* built-in. The method is provided so that subclasses can override it.

convert_field(*value*, *conversion*)

Converts the value (returned by *get_field()*) given a conversion type (as in the tuple returned by the *parse()* method). The default version understands 's' (str), 'r' (repr) and 'a' (ascii) conversion types.

6.1.3 Format String Syntax

The *str.format()* method and the *Formatter* class share the same syntax for format strings (although in the case of *Formatter*, subclasses can define their own format string syntax). The syntax is related to that of formatted string literals, but it is less sophisticated and, in particular, does not support arbitrary expressions.

Format strings contain "replacement fields" surrounded by curly braces `{}`. Anything that is not contained in braces is considered literal text, which is copied unchanged to the output. If you need to include a brace character in the literal text, it can be escaped by doubling: `{{` and `}}`.

The grammar for a replacement field is as follows:

```
replacement_field ::= "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name        ::= arg_name ("." attribute_name | "[" element_index "]")*
arg_name          ::= [identifier | digit+]
attribute_name    ::= identifier
element_index     ::= digit+ | index_string
index_string      ::= <any source character except "]"> +
conversion        ::= "r" | "s" | "a"
format_spec       ::= format-spec:format_spec
```

In less formal terms, the replacement field can start with a *field_name* that specifies the object whose value is to be formatted and inserted into the output instead of the replacement field. The *field_name* is optionally followed by a *conversion* field, which is preceded by an exclamation point `'!'`, and a *format_spec*, which is preceded by a colon `':'`. These specify a non-default format for the replacement value.

See also the *Format Specification Mini-Language* section.

The *field_name* itself begins with an *arg_name* that is either a number or a keyword. If it's a number, it refers to a positional argument, and if it's a keyword, it refers to a named keyword argument. An *arg_name* is treated as a number if a call to *str.isdecimal()* on the string would return true. If the numerical arg_names in a format string are 0, 1, 2, … in sequence, they can all be omitted (not just some) and the numbers 0, 1, 2, … will be automatically inserted in that order. Because *arg_name* is not quote-delimited, it is not possible to specify arbitrary dictionary keys (e.g., the strings `'10'` or `':-]'`) within a format string. The *arg_name* can be followed by any number of index or attribute expressions. An expression of the form `'.name'` selects the named attribute using *getattr()*, while an expression of the form `'[index]'` does an index lookup using `__getitem__()`.

Changed in version 3.1: The positional argument specifiers can be omitted for *str.format()*, so `'{} {}'.format(a, b)` is equivalent to `'{0} {1}'.format(a, b)`.

Changed in version 3.4: The positional argument specifiers can be omitted for *Formatter*.

Some simple format string examples:

```
"First, thou shalt count to {0}"  # References first positional argument
"Bring me a {}"                   # Implicitly references the first positional␣
↪argument
"From {} to {}"                   # Same as "From {0} to {1}"
"My quest is {name}"              # References keyword argument 'name'
"Weight in tons {0.weight}"       # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}"   # First element of keyword argument 'players'.
```

The *conversion* field causes a type coercion before formatting. Normally, the job of formatting a value is done by the `__format__()` method of the value itself. However, in some cases it is desirable to force a type to be formatted as a string, overriding its own definition of formatting. By converting the value to a string before calling `__format__()`, the normal formatting logic is bypassed.

Three conversion flags are currently supported: `'!s'` which calls *str()* on the value, `'!r'` which calls *repr()* and `'!a'` which calls *ascii()*.

Some examples:

```
"Harold's a clever {0!s}"         # Calls str() on the argument first
"Bring out the holy {name!r}"     # Calls repr() on the argument first
"More {!a}"                       # Calls ascii() on the argument first
```

The *format_spec* field contains a specification of how the value should be presented, including such details as field width, alignment, padding, decimal precision and so on. Each value type can define its own "formatting mini-language" or interpretation of the *format_spec*.

Most built-in types support a common formatting mini-language, which is described in the next section.

A *format_spec* field can also include nested replacement fields within it. These nested replacement fields may contain a field name, conversion flag and format specification, but deeper nesting is not allowed. The replacement fields within the format_spec are substituted before the *format_spec* string is interpreted. This allows the formatting of a value to be dynamically specified.

See the *Format examples* section for some examples.

Format Specification Mini-Language

"Format specifications" are used within replacement fields contained within a format string to define how individual values are presented (see *Format String Syntax* and f-strings). They can also be passed directly to the built-in *format()* function. Each formattable type may define how the format specification is to be interpreted.

Most built-in types implement the following options for format specifications, although some of the formatting options are only supported by the numeric types.

A general convention is that an empty format specification produces the same result as if you had called *str()* on the value. A non-empty format specification typically modifies the result.

The general form of a *standard format specifier* is:

```
format_spec ::= [options][width][grouping]["." precision][type]
options     ::= [[fill]align][sign]["z"]["#"]["0"]
fill        ::= <any character>
align       ::= "<" | ">" | "=" | "^"
sign        ::= "+" | "-" | " "
width       ::= digit+
grouping    ::= "," | "_"
precision   ::= digit+
```

```
type          ::= "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g"
                | "G" | "n" | "o" | "s" | "x" | "X" | "%"
```

If a valid *align* value is specified, it can be preceded by a *fill* character that can be any character and defaults to a space if omitted. It is not possible to use a literal curly brace ("`{`" or "`}`") as the *fill* character in a formatted string literal or when using the *str.format()* method. However, it is possible to insert a curly brace with a nested replacement field. This limitation doesn't affect the *format()* function.

The meaning of the various alignment options is as follows:

Option	Meaning
`'<'`	Forces the field to be left-aligned within the available space (this is the default for most objects).
`'>'`	Forces the field to be right-aligned within the available space (this is the default for numbers).
`'='`	Forces the padding to be placed after the sign (if any) but before the digits. This is used for printing fields in the form '+000000120'. This alignment option is only valid for numeric types, excluding *complex*. It becomes the default for numbers when '0' immediately precedes the field width.
`'^'`	Forces the field to be centered within the available space.

Note that unless a minimum field width is defined, the field width will always be the same size as the data to fill it, so that the alignment option has no meaning in this case.

The *sign* option is only valid for number types, and can be one of the following:

Option	Meaning
`'+'`	Indicates that a sign should be used for both positive as well as negative numbers.
`'-'`	Indicates that a sign should be used only for negative numbers (this is the default behavior).
space	Indicates that a leading space should be used on positive numbers, and a minus sign on negative numbers.

The `'z'` option coerces negative zero floating-point values to positive zero after rounding to the format precision. This option is only valid for floating-point presentation types.

Changed in version 3.11: Added the `'z'` option (see also **PEP 682**).

The `'#'` option causes the "alternate form" to be used for the conversion. The alternate form is defined differently for different types. This option is only valid for integer, float and complex types. For integers, when binary, octal, or hexadecimal output is used, this option adds the respective prefix `'0b'`, `'0o'`, `'0x'`, or `'0X'` to the output value. For float and complex the alternate form causes the result of the conversion to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for `'g'` and `'G'` conversions, trailing zeros are not removed from the result.

The *width* is a decimal integer defining the minimum total field width, including any prefixes, separators, and other formatting characters. If not specified, then the field width will be determined by the content.

When no explicit alignment is given, preceding the *width* field by a zero (`'0'`) character enables sign-aware zero-padding for numeric types, excluding *complex*. This is equivalent to a *fill* character of `'0'` with an *alignment* type of `'='`.

Changed in version 3.10: Preceding the *width* field by `'0'` no longer affects the default alignment for strings.

The *grouping* option after the *width* field specifies a digit group separator for the integral part of a number. It can be one of the following:

Option	Meaning
`','`	Inserts a comma every 3 digits for integer presentation type `'d'` and floating-point presentation types, excluding `'n'`. For other presentation types, this option is not supported.
`'_'`	Inserts an underscore every 3 digits for integer presentation type `'d'` and floating-point presentation types, excluding `'n'`. For integer presentation types `'b'`, `'o'`, `'x'`, and `'X'`, underscores are inserted every 4 digits. For other presentation types, this option is not supported.

For a locale aware separator, use the `'n'` presentation type instead.

Changed in version 3.1: Added the `','` option (see also **PEP 378**).

Changed in version 3.6: Added the `'_'` option (see also **PEP 515**).

The *precision* is a decimal integer indicating how many digits should be displayed after the decimal point for presentation types `'f'` and `'F'`, or before and after the decimal point for presentation types `'g'` or `'G'`. For string presentation types the field indicates the maximum field size - in other words, how many characters will be used from the field content. The *precision* is not allowed for integer presentation types.

Finally, the *type* determines how the data should be presented.

The available string presentation types are:

Type	Meaning
`'s'`	String format. This is the default type for strings and may be omitted.
None	The same as `'s'`.

The available integer presentation types are:

Type	Meaning
`'b'`	Binary format. Outputs the number in base 2.
`'c'`	Character. Converts the integer to the corresponding unicode character before printing.
`'d'`	Decimal Integer. Outputs the number in base 10.
`'o'`	Octal format. Outputs the number in base 8.
`'x'`	Hex format. Outputs the number in base 16, using lower-case letters for the digits above 9.
`'X'`	Hex format. Outputs the number in base 16, using upper-case letters for the digits above 9. In case `'#'` is specified, the prefix `'0x'` will be upper-cased to `'0X'` as well.
`'n'`	Number. This is the same as `'d'`, except that it uses the current locale setting to insert the appropriate digit group separators.
None	The same as `'d'`.

In addition to the above presentation types, integers can be formatted with the floating-point presentation types listed below (except `'n'` and `None`). When doing so, *`float()`* is used to convert the integer to a floating-point number before formatting.

The available presentation types for *`float`* and *`Decimal`* values are:

Type	Meaning
`'e'`	Scientific notation. For a given precision `p`, formats the number in scientific notation with the letter 'e' separating the coefficient from the exponent. The coefficient has one digit before and `p` digits after the decimal point, for a total of `p + 1` significant digits. With no precision given, uses a precision of `6` digits after the decimal point for *`float`*, and shows all coefficient digits for *`Decimal`*. If `p=0`, the decimal point is omitted unless the `#` option is used.
`'E'`	Scientific notation. Same as `'e'` except it uses an upper case 'E' as the separator character.
`'f'`	Fixed-point notation. For a given precision `p`, formats the number as a decimal number with exactly `p` digits following the decimal point. With no precision given, uses a precision of `6` digits after the decimal point for *`float`*, and uses a precision large enough to show all coefficient digits for *`Decimal`*. If `p=0`, the decimal point is omitted unless the `#` option is used.
`'F'`	Fixed-point notation. Same as `'f'`, but converts `nan` to `NAN` and `inf` to `INF`.
`'g'`	General format. For a given precision `p >= 1`, this rounds the number to `p` significant digits and then formats the result in either fixed-point format or in scientific notation, depending on its magnitude. A precision of `0` is treated as equivalent to a precision of `1`. The precise rules are as follows: suppose that the result formatted with presentation type `'e'` and precision `p-1` would have exponent `exp`. Then, if `m <= exp < p`, where `m` is -4 for floats and -6 for *`Decimals`*, the number is formatted with presentation type `'f'` and precision `p-1-exp`. Otherwise, the number is formatted with presentation type `'e'` and precision `p-1`. In both cases insignificant trailing zeros are removed from the significand, and the decimal point is also removed if there are no remaining digits following it, unless the `'#'` option is used. With no precision given, uses a precision of `6` significant digits for *`float`*. For *`Decimal`*, the coefficient of the result is formed from the coefficient digits of the value; scientific notation is used for values smaller than `1e-6` in absolute value and values where the place value of the least significant digit is larger than 1, and fixed-point notation is used otherwise. Positive and negative infinity, positive and negative zero, and nans, are formatted as `inf`, `-inf`, `0`, `-0` and `nan` respectively, regardless of the precision.
`'G'`	General format. Same as `'g'` except switches to `'E'` if the number gets too large. The representations of infinity and NaN are uppercased, too.
`'n'`	Number. This is the same as `'g'`, except that it uses the current locale setting to insert the appropriate digit group separators for the integral part of a number.
`'%'`	Percentage. Multiplies the number by 100 and displays in fixed (`'f'`) format, followed by a percent sign.
None	For *`float`* this is like the `'g'` type, except that when fixed-point notation is used to format the result, it always includes at least one digit past the decimal point, and switches to the scientific notation when `exp >= p - 1`. When the precision is not specified, the latter will be as large as needed to represent the given value faithfully. For *`Decimal`*, this is the same as either `'g'` or `'G'` depending on the value of `context.capitals` for the current decimal context. The overall effect is to match the output of *`str()`* as altered by the other format modifiers.

The result should be correctly rounded to a given precision `p` of digits after the decimal point. The rounding mode for *`float`* matches that of the *`round()`* builtin. For *`Decimal`*, the rounding mode of the current *context* will be used.

The available presentation types for *`complex`* are the same as those for *`float`* (`'%'` is not allowed). Both the real and imaginary components of a complex number are formatted as floating-point numbers, according to the specified presentation type. They are separated by the mandatory sign of the imaginary part, the latter being terminated by a `j` suffix. If the presentation type is missing, the result will match the output of *`str()`* (complex numbers with a non-zero real part are also surrounded by parentheses), possibly altered by other format modifiers.

Format examples

This section contains examples of the *str.format()* syntax and comparison with the old `%`-formatting.

In most of the cases the syntax is similar to the old `%`-formatting, with the addition of the `{}` and with `:` used instead of `%`. For example, `'%03.2f'` can be translated to `'{:03.2f}'`.

The new format syntax also supports new and different options, shown in the following examples.

Accessing arguments by position:

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{}, {}, {}'.format('a', 'b', 'c')  # 3.1+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc')      # unpacking argument sequence
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad')   # arguments' indices can be repeated
'abracadabra'
```

Accessing arguments by name:

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-
↪115.81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

Accessing arguments' attributes:

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
...  'and the imaginary part {0.imag}.').format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part␣
↪-5.0.'
>>> class Point:
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

Accessing arguments' items:

```
>>> coord = (3, 5)
>>> 'X: {0[0]};  Y: {0[1]}'.format(coord)
'X: 3;  Y: 5'
```

Replacing `%s` and `%r`:

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
"repr() shows quotes: 'test1'; str() doesn't: test2"
```

Aligning the text and specifying a width:

```
>>> '{:<30}'.format('left aligned')
'left aligned                  '
>>> '{:>30}'.format('right aligned')
'                 right aligned'
>>> '{:^30}'.format('centered')
'           centered           '
>>> '{:*^30}'.format('centered')  # use '*' as a fill char
'***********centered***********'
```

Replacing `%+f`, `%-f`, and `% f` and specifying a sign:

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14)  # show it always
'+3.140000; -3.140000'
>>> '{: f}; {: f}'.format(3.14, -3.14)  # show a space for positive numbers
' 3.140000; -3.140000'
>>> '{:-f}; {:-f}'.format(3.14, -3.14)  # show only the minus -- same as '{:f}; {:f}'
'3.140000; -3.140000'
```

Replacing `%x` and `%o` and converting the value to different bases:

```
>>> # format also supports binary numbers
>>> "int: {0:d};  hex: {0:x};  oct: {0:o};  bin: {0:b}".format(42)
'int: 42;  hex: 2a;  oct: 52;  bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
>>> "int: {0:d};  hex: {0:#x};  oct: {0:#o};  bin: {0:#b}".format(42)
'int: 42;  hex: 0x2a;  oct: 0o52;  bin: 0b101010'
```

Using the comma or the underscore as a digit group separator:

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
>>> '{:_}'.format(1234567890)
'1_234_567_890'
>>> '{:_b}'.format(1234567890)
'100_1001_1001_0110_0000_0010_1101_0010'
>>> '{:_x}'.format(1234567890)
'4996_02d2'
```

Expressing a percentage:

```
>>> points = 19
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 86.36%'
```

Using type-specific formatting:

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

Nesting arguments and more complex examples:

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, align=align)
...
```

(continues on next page)

(continued from previous page)

```
'left<<<<<<<<<<<'
'^^^^^center^^^^^'
'>>>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
'C0A80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print('{0:{width}{base}}'.format(num, base=base, width=width), end=' ')
...     print()
...
    5     5     5   101
    6     6     6   110
    7     7     7   111
    8     8    10  1000
    9     9    11  1001
   10     A    12  1010
   11     B    13  1011
```

6.1.4 Template strings

Template strings provide simpler string substitutions as described in **PEP 292**. A primary use case for template strings is for internationalization (i18n) since in that context, the simpler syntax and functionality makes it easier to translate than other built-in string formatting facilities in Python. As an example of a library built on template strings for i18n, see the flufl.i18n package.

Template strings support `$`-based substitutions, using the following rules:

- `$$` is an escape; it is replaced with a single `$`.
- `$identifier` names a substitution placeholder matching a mapping key of `"identifier"`. By default, `"identifier"` is restricted to any case-insensitive ASCII alphanumeric string (including underscores) that starts with an underscore or ASCII letter. The first non-identifier character after the `$` character terminates this placeholder specification.
- `${identifier}` is equivalent to `$identifier`. It is required when valid identifier characters follow the placeholder but are not part of the placeholder, such as `"${noun}ification"`.

Any other appearance of `$` in the string will result in a *ValueError* being raised.

The *string* module provides a *Template* class that implements these rules. The methods of *Template* are:

class string.**Template**(*template*)

The constructor takes a single argument which is the template string.

substitute(*mapping={}*, */*, ***kwds*)

Performs the template substitution, returning a new string. *mapping* is any dictionary-like object with keys that match the placeholders in the template. Alternatively, you can provide keyword arguments, where the keywords are the placeholders. When both *mapping* and *kwds* are given and there are duplicates, the placeholders from *kwds* take precedence.

safe_substitute(*mapping={}*, */*, ***kwds*)

Like *substitute()*, except that if placeholders are missing from *mapping* and *kwds*, instead of raising a *KeyError* exception, the original placeholder will appear in the resulting string intact. Also, unlike with *substitute()*, any other appearances of the `$` will simply return `$` instead of raising *ValueError*.

While other exceptions may still occur, this method is called "safe" because it always tries to return a usable string instead of raising an exception. In another sense, *safe_substitute()* may be anything other than safe, since it will silently ignore malformed templates containing dangling delimiters, unmatched braces, or placeholders that are not valid Python identifiers.

is_valid()

Returns `False` if the template has invalid placeholders that will cause *substitute()* to raise *ValueError*.

Added in version 3.11.

get_identifiers()

Returns a list of the valid identifiers in the template, in the order they first appear, ignoring any invalid identifiers.

Added in version 3.11.

Template instances also provide one public data attribute:

template

This is the object passed to the constructor's *template* argument. In general, you shouldn't change it, but read-only access is not enforced.

Here is an example of how to use a Template:

```
>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

Advanced usage: you can derive subclasses of *Template* to customize the placeholder syntax, delimiter character, or the entire regular expression used to parse template strings. To do this, you can override these class attributes:

- *delimiter* – This is the literal string describing a placeholder introducing delimiter. The default value is `$`. Note that this should *not* be a regular expression, as the implementation will call *re.escape()* on this string as needed. Note further that you cannot change the delimiter after class creation (i.e. a different delimiter must be set in the subclass's class namespace).
- *idpattern* – This is the regular expression describing the pattern for non-braced placeholders. The default value is the regular expression `(?a:[_a-z][_a-z0-9]*)`. If this is given and *braceidpattern* is `None` this pattern will also apply to braced placeholders.

> **Note**
>
> Since default *flags* is `re.IGNORECASE`, pattern `[a-z]` can match with some non-ASCII characters. That's why we use the local `a` flag here.

Changed in version 3.7: *braceidpattern* can be used to define separate patterns used inside and outside the braces.

- *braceidpattern* – This is like *idpattern* but describes the pattern for braced placeholders. Defaults to `None` which means to fall back to *idpattern* (i.e. the same pattern is used both inside and outside braces). If given, this allows you to define different patterns for braced and unbraced placeholders.

  Added in version 3.7.

- *flags* – The regular expression flags that will be applied when compiling the regular expression used for recognizing substitutions. The default value is `re.IGNORECASE`. Note that `re.VERBOSE` will always be added to the flags, so custom *idpattern*s must follow conventions for verbose regular expressions.

  Added in version 3.2.

Alternatively, you can provide the entire regular expression pattern by overriding the class attribute *pattern*. If you do this, the value must be a regular expression object with four named capturing groups. The capturing groups correspond to the rules given above, along with the invalid placeholder rule:

- *escaped* – This group matches the escape sequence, e.g. `$$`, in the default pattern.
- *named* – This group matches the unbraced placeholder name; it should not include the delimiter in capturing group.
- *braced* – This group matches the brace enclosed placeholder name; it should not include either the delimiter or braces in the capturing group.
- *invalid* – This group matches any other delimiter pattern (usually a single delimiter), and it should appear last in the regular expression.

The methods on this class will raise *ValueError* if the pattern matches the template without one of these named groups matching.

6.1.5 Helper functions

`string.`**`capwords`**(*s*, *sep=None*)

Split the argument into words using *str.split()*, capitalize each word using *str.capitalize()*, and join the capitalized words using *str.join()*. If the optional second argument *sep* is absent or `None`, runs of whitespace characters are replaced by a single space and leading and trailing whitespace are removed, otherwise *sep* is used to split and join the words.

6.2 `re` — Regular expression operations

Source code: Lib/re/

This module provides regular expression matching operations similar to those found in Perl.

Both patterns and strings to be searched can be Unicode strings (*str*) as well as 8-bit strings (*bytes*). However, Unicode strings and 8-bit strings cannot be mixed: that is, you cannot match a Unicode string with a bytes pattern or vice-versa; similarly, when asking for a substitution, the replacement string must be of the same type as both the pattern and the search string.

Regular expressions use the backslash character (`'\'`) to indicate special forms or to allow special characters to be used without invoking their special meaning. This collides with Python's usage of the same character for the same purpose in string literals; for example, to match a literal backslash, one might have to write `'\\\\'` as the pattern string, because the regular expression must be `\\`, and each backslash must be expressed as `\\` inside a regular Python string literal. Also, please note that any invalid escape sequences in Python's usage of the backslash in string literals now generate a *SyntaxWarning* and in the future this will become a *SyntaxError*. This behaviour will happen even if it is a valid escape sequence for a regular expression.

The solution is to use Python's raw string notation for regular expression patterns; backslashes are not handled in any special way in a string literal prefixed with `'r'`. So `r"\n"` is a two-character string containing `'\'` and `'n'`, while `"\n"` is a one-character string containing a newline. Usually patterns will be expressed in Python code using this raw string notation.

It is important to note that most regular expression operations are available as module-level functions and methods on *compiled regular expressions*. The functions are shortcuts that don't require you to compile a regex object first, but miss some fine-tuning parameters.

See also

The third-party regex module, which has an API compatible with the standard library `re` module, but offers additional functionality and a more thorough Unicode support.

6.2.1 Regular Expression Syntax

A regular expression (or RE) specifies a set of strings that matches it; the functions in this module let you check if a particular string matches a given regular expression (or if a given regular expression matches a particular string, which comes down to the same thing).

Regular expressions can be concatenated to form new regular expressions; if *A* and *B* are both regular expressions, then *AB* is also a regular expression. In general, if a string *p* matches *A* and another string *q* matches *B*, the string *pq* will match AB. This holds unless *A* or *B* contain low precedence operations; boundary conditions between *A* and *B*; or have numbered group references. Thus, complex expressions can easily be constructed from simpler primitive expressions like the ones described here. For details of the theory and implementation of regular expressions, consult the Friedl book [Frie09], or almost any textbook about compiler construction.

A brief explanation of the format of regular expressions follows. For further information and a gentler presentation, consult the regex-howto.

Regular expressions can contain both special and ordinary characters. Most ordinary characters, like `'A'`, `'a'`, or `'0'`, are the simplest regular expressions; they simply match themselves. You can concatenate ordinary characters, so `last` matches the string `'last'`. (In the rest of this section, we'll write RE's in `this special style`, usually without quotes, and strings to be matched `'in single quotes'`.)

Some characters, like `'|'` or `'('`, are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted.

Repetition operators or quantifiers (`*`, `+`, `?`, `{m,n}`, etc) cannot be directly nested. This avoids ambiguity with the non-greedy modifier suffix `?`, and with other modifiers in other implementations. To apply a second repetition to an inner repetition, parentheses may be used. For example, the expression `(?:a{6})*` matches any multiple of six `'a'` characters.

The special characters are:

`.`
: (Dot.) In the default mode, this matches any character except a newline. If the *DOTALL* flag has been specified, this matches any character including a newline. `(?s:.)` matches any character regardless of flags.

`^`
: (Caret.) Matches the start of the string, and in *MULTILINE* mode also matches immediately after each newline.

`$`
: Matches the end of the string or just before the newline at the end of the string, and in *MULTILINE* mode also matches before a newline. `foo` matches both 'foo' and 'foobar', while the regular expression `foo$` matches only 'foo'. More interestingly, searching for `foo.$` in `'foo1\nfoo2\n'` matches 'foo2' normally, but 'foo1' in *MULTILINE* mode; searching for a single `$` in `'foo\n'` will find two (empty) matches: one just before the newline, and one at the end of the string.

`*`
: Causes the resulting RE to match 0 or more repetitions of the preceding RE, as many repetitions as are possible. `ab*` will match 'a', 'ab', or 'a' followed by any number of 'b's.

`+`
: Causes the resulting RE to match 1 or more repetitions of the preceding RE. `ab+` will match 'a' followed by any non-zero number of 'b's; it will not match just 'a'.

?

Causes the resulting RE to match 0 or 1 repetitions of the preceding RE. `ab?` will match either 'a' or 'ab'.

***?, +?, ??**

The `'*'`, `'+'`, and `'?'` quantifiers are all *greedy*; they match as much text as possible. Sometimes this behaviour isn't desired; if the RE `<.*>` is matched against `'<a> b <c>'`, it will match the entire string, and not just `'<a>'`. Adding `?` after the quantifier makes it perform the match in *non-greedy* or *minimal* fashion; as *few* characters as possible will be matched. Using the RE `<.*?>` will match only `'<a>'`.

***+, ++, ?+**

Like the `'*'`, `'+'`, and `'?'` quantifiers, those where `'+'` is appended also match as many times as possible. However, unlike the true greedy quantifiers, these do not allow back-tracking when the expression following it fails to match. These are known as *possessive* quantifiers. For example, `a*a` will match `'aaaa'` because the `a*` will match all 4 `'a'`s, but, when the final `'a'` is encountered, the expression is backtracked so that in the end the `a*` ends up matching 3 `'a'`s total, and the fourth `'a'` is matched by the final `'a'`. However, when `a*+a` is used to match `'aaaa'`, the `a*+` will match all 4 `'a'`, but when the final `'a'` fails to find any more characters to match, the expression cannot be backtracked and will thus fail to match. `x*+`, `x++` and `x?+` are equivalent to `(?>x*)`, `(?>x+)` and `(?>x?)` correspondingly.

Added in version 3.11.

{m}

Specifies that exactly *m* copies of the previous RE should be matched; fewer matches cause the entire RE not to match. For example, `a{6}` will match exactly six `'a'` characters, but not five.

{m,n}

Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as many repetitions as possible. For example, `a{3,5}` will match from 3 to 5 `'a'` characters. Omitting *m* specifies a lower bound of zero, and omitting *n* specifies an infinite upper bound. As an example, `a{4,}b` will match `'aaaab'` or a thousand `'a'` characters followed by a `'b'`, but not `'aaab'`. The comma may not be omitted or the modifier would be confused with the previously described form.

{m,n}?

Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as *few* repetitions as possible. This is the non-greedy version of the previous quantifier. For example, on the 6-character string `'aaaaaa'`, `a{3,5}` will match 5 `'a'` characters, while `a{3,5}?` will only match 3 characters.

{m,n}+

Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as many repetitions as possible *without* establishing any backtracking points. This is the possessive version of the quantifier above. For example, on the 6-character string `'aaaaaa'`, `a{3,5}+aa` attempt to match 5 `'a'` characters, then, requiring 2 more `'a'`s, will need more characters than available and thus fail, while `a{3,5}aa` will match with `a{3,5}` capturing 5, then 4 `'a'`s by backtracking and then the final 2 `'a'`s are matched by the final `aa` in the pattern. `x{m,n}+` is equivalent to `(?>x{m,n})`.

Added in version 3.11.

****

Either escapes special characters (permitting you to match characters like `'*'`, `'?'`, and so forth), or signals a special sequence; special sequences are discussed below.

If you're not using a raw string to express the pattern, remember that Python also uses the backslash as an escape sequence in string literals; if the escape sequence isn't recognized by Python's parser, the backslash and subsequent character are included in the resulting string. However, if Python would recognize the resulting sequence, the backslash should be repeated twice. This is complicated and hard to understand, so it's highly recommended that you use raw strings for all but the simplest expressions.

[]

Used to indicate a set of characters. In a set:

- Characters can be listed individually, e.g. `[amk]` will match `'a'`, `'m'`, or `'k'`.
- Ranges of characters can be indicated by giving two characters and separating them by a `'-'`, for example `[a-z]` will match any lowercase ASCII letter, `[0-5][0-9]` will match all the two-digits numbers from

`00` to `59`, and `[0-9A-Fa-f]` will match any hexadecimal digit. If `-` is escaped (e.g. `[a\-z]`) or if it's placed as the first or last character (e.g. `[-a]` or `[a-]`), it will match a literal `'-'`.

- Special characters except backslash lose their special meaning inside sets. For example, `[(+*)]` will match any of the literal characters `'('`, `'+'`, `'*'`, or `')'`.
- Backslash either escapes characters which have special meaning in a set such as `'-'`, `']'`, `'^'` and `'\\'` itself or signals a special sequence which represents a single character such as `\xa0` or `\n` or a character class such as `\w` or `\S` (defined below). Note that `\b` represents a single "backspace" character, not a word boundary as outside a set, and numeric escapes such as `\1` are always octal escapes, not group references. Special sequences which do not match a single character such as `\A` and `\Z` are not allowed.
- Characters that are not within a range can be matched by *complementing* the set. If the first character of the set is `'^'`, all the characters that are *not* in the set will be matched. For example, `[^5]` will match any character except `'5'`, and `[^^]` will match any character except `'^'`. `^` has no special meaning if it's not the first character in the set.
- To match a literal `']'` inside a set, precede it with a backslash, or place it at the beginning of the set. For example, both `[()[\]{}]` and `[]()[{}]` will match a right bracket, as well as left bracket, braces, and parentheses.
- Support of nested sets and set operations as in Unicode Technical Standard #18 might be added in the future. This would change the syntax, so to facilitate this change a *FutureWarning* will be raised in ambiguous cases for the time being. That includes sets starting with a literal `'['` or containing literal character sequences `'--'`, `'&&'`, `'~~'`, and `'||'`. To avoid a warning escape them with a backslash.

Changed in version 3.7: *FutureWarning* is raised if a character set contains constructs that will change semantically in the future.

|

`A|B`, where *A* and *B* can be arbitrary REs, creates a regular expression that will match either *A* or *B*. An arbitrary number of REs can be separated by the `'|'` in this way. This can be used inside groups (see below) as well. As the target string is scanned, REs separated by `'|'` are tried from left to right. When one pattern completely matches, that branch is accepted. This means that once *A* matches, *B* will not be tested further, even if it would produce a longer overall match. In other words, the `'|'` operator is never greedy. To match a literal `'|'`, use `\|`, or enclose it inside a character class, as in `[|]`.

(...)

Matches whatever regular expression is inside the parentheses, and indicates the start and end of a group; the contents of a group can be retrieved after a match has been performed, and can be matched later in the string with the `\number` special sequence, described below. To match the literals `'('` or `')'`, use `\(` or `\)`, or enclose them inside a character class: `[(]`, `[)]`.

(?...)

This is an extension notation (a `'?'` following a `'('` is not meaningful otherwise). The first character after the `'?'` determines what the meaning and further syntax of the construct is. Extensions usually do not create a new group; `(?P<name>...)` is the only exception to this rule. Following are the currently supported extensions.

(?aiLmsux)

(One or more letters from the set `'a'`, `'i'`, `'L'`, `'m'`, `'s'`, `'u'`, `'x'`.) The group matches the empty string; the letters set the corresponding flags for the entire regular expression:

- *re.A* (ASCII-only matching)
- *re.I* (ignore case)
- *re.L* (locale dependent)
- *re.M* (multi-line)
- *re.S* (dot matches all)
- *re.U* (Unicode matching)
- *re.X* (verbose)

(The flags are described in *Module Contents*.) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the `re.compile()` function. Flags should be used first in the expression string.

Changed in version 3.11: This construction can only be used at the start of the expression.

(?:...)
A non-capturing version of regular parentheses. Matches whatever regular expression is inside the parentheses, but the substring matched by the group *cannot* be retrieved after performing a match or referenced later in the pattern.

(?aiLmsux-imsx:...)
(Zero or more letters from the set `'a'`, `'i'`, `'L'`, `'m'`, `'s'`, `'u'`, `'x'`, optionally followed by `'-'` followed by one or more letters from the `'i'`, `'m'`, `'s'`, `'x'`.) The letters set or remove the corresponding flags for the part of the expression:

- `re.A` (ASCII-only matching)
- `re.I` (ignore case)
- `re.L` (locale dependent)
- `re.M` (multi-line)
- `re.S` (dot matches all)
- `re.U` (Unicode matching)
- `re.X` (verbose)

(The flags are described in *Module Contents*.)

The letters `'a'`, `'L'` and `'u'` are mutually exclusive when used as inline flags, so they can't be combined or follow `'-'`. Instead, when one of them appears in an inline group, it overrides the matching mode in the enclosing group. In Unicode patterns `(?a:...)` switches to ASCII-only matching, and `(?u:...)` switches to Unicode matching (default). In bytes patterns `(?L:...)` switches to locale dependent matching, and `(?a:...)` switches to ASCII-only matching (default). This override is only in effect for the narrow inline group, and the original matching mode is restored outside of the group.

Added in version 3.6.

Changed in version 3.7: The letters `'a'`, `'L'` and `'u'` also can be used in a group.

(?>...)
Attempts to match `...` as if it was a separate regular expression, and if successful, continues to match the rest of the pattern following it. If the subsequent pattern fails to match, the stack can only be unwound to a point *before* the `(?>...)` because once exited, the expression, known as an *atomic group*, has thrown away all stack points within itself. Thus, `(?>.*).` would never match anything because first the `.*` would match all characters possible, then, having nothing left to match, the final `.` would fail to match. Since there are no stack points saved in the Atomic Group, and there is no stack point before it, the entire expression would thus fail to match.

Added in version 3.11.

(?P<name>...)
Similar to regular parentheses, but the substring matched by the group is accessible via the symbolic group name *name*. Group names must be valid Python identifiers, and in `bytes` patterns they can only contain bytes in the ASCII range. Each group name must be defined only once within a regular expression. A symbolic group is also a numbered group, just as if the group were not named.

Named groups can be referenced in three contexts. If the pattern is `(?P<quote>['"]).*?(?P=quote)` (i.e. matching a string quoted with either single or double quotes):

Context of reference to group "quote"	Ways to reference it
in the same pattern itself	• `(?P=quote)` (as shown) • `\1`
when processing match object *m*	• `m.group('quote')` • `m.end('quote')` (etc.)
in a string passed to the *repl* argument of `re.sub()`	• `\g<quote>` • `\g<1>` • `\1`

Changed in version 3.12: In *bytes* patterns, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

(?P=name)
A backreference to a named group; it matches whatever text was matched by the earlier group named *name*.

(?#...)
A comment; the contents of the parentheses are simply ignored.

(?=...)
Matches if `...` matches next, but doesn't consume any of the string. This is called a *lookahead assertion*. For example, `Isaac (?=Asimov)` will match `'Isaac '` only if it's followed by `'Asimov'`.

(?!...)
Matches if `...` doesn't match next. This is a *negative lookahead assertion*. For example, `Isaac (?!Asimov)` will match `'Isaac '` only if it's *not* followed by `'Asimov'`.

(?<=...)
Matches if the current position in the string is preceded by a match for `...` that ends at the current position. This is called a *positive lookbehind assertion*. `(?<=abc)def` will find a match in `'abcdef'`, since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that `abc` or `a|b` are allowed, but `a*` and `a{3,4}` are not. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the *search()* function rather than the *match()* function:

```
>>> import re
>>> m = re.search('(?<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

This example looks for a word following a hyphen:

```
>>> m = re.search(r'(?<=-)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

Changed in version 3.5: Added support for group references of fixed length.

(?<!...)
Matches if the current position in the string is not preceded by a match for `...`. This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

(?(id/name)yes-pattern|no-pattern)
Will try to match with `yes-pattern` if the group with given *id* or *name* exists, and with `no-pattern` if

it doesn't. `no-pattern` is optional and can be omitted. For example, `(<)?(\w+@\w+(?:\.\w+)+)(?(1)>|$)` is a poor email matching pattern, which will match with `'<user@host.com>'` as well as `'user@host.com'`, but not with `'<user@host.com'` nor `'user@host.com>'`.

Changed in version 3.12: Group *id* can only contain ASCII digits. In *bytes* patterns, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not an ASCII digit or an ASCII letter, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

\number

Matches the contents of the group of the same number. Groups are numbered starting from 1. For example, `(.+) \1` matches `'the the'` or `'55 55'`, but not `'thethe'` (note the space after the group). This special sequence can only be used to match one of the first 99 groups. If the first digit of *number* is 0, or *number* is 3 octal digits long, it will not be interpreted as a group match, but as the character with octal value *number*. Inside the `'['` and `']'` of a character class, all numeric escapes are treated as characters.

\A

Matches only at the start of the string.

\b

Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of word characters. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning or end of the string. This means that `r'\bat\b'` matches `'at'`, `'at.'`, `'(at)'`, and `'as at ay'` but not `'attempt'` or `'atlas'`.

The default word characters in Unicode (str) patterns are Unicode alphanumerics and the underscore, but this can be changed by using the *ASCII* flag. Word boundaries are determined by the current locale if the *LOCALE* flag is used.

> **Note**
>
> Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

\B

Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'at\B'` matches `'athens'`, `'atom'`, `'attorney'`, but not `'at'`, `'at.'`, or `'at!'`. `\B` is the opposite of `\b`, so word characters in Unicode (str) patterns are Unicode alphanumerics or the underscore, although this can be changed by using the *ASCII* flag. Word boundaries are determined by the current locale if the *LOCALE* flag is used.

> **Note**
>
> Note that `\B` does not match an empty string, which differs from RE implementations in other programming languages such as Perl. This behavior is kept for compatibility reasons.

\d

For Unicode (str) patterns:

Matches any Unicode decimal digit (that is, any character in Unicode character category [Nd]). This includes `[0-9]`, and also many other digit characters.

Matches `[0-9]` if the *ASCII* flag is used.

For 8-bit (bytes) patterns:

Matches any decimal digit in the ASCII character set; this is equivalent to `[0-9]`.

\D

Matches any character which is not a decimal digit. This is the opposite of `\d`.

Matches `[^0-9]` if the *ASCII* flag is used.

\s

For Unicode (str) patterns:
Matches Unicode whitespace characters (as defined by *str.isspace()*). This includes `[ \t\n\r\f\v]`, and also many other characters, for example the non-breaking spaces mandated by typography rules in many languages.

Matches `[ \t\n\r\f\v]` if the *ASCII* flag is used.

For 8-bit (bytes) patterns:
Matches characters considered whitespace in the ASCII character set; this is equivalent to `[ \t\n\r\f\v]`.

\S

Matches any character which is not a whitespace character. This is the opposite of `\s`.

Matches `[^ \t\n\r\f\v]` if the *ASCII* flag is used.

\w

For Unicode (str) patterns:
Matches Unicode word characters; this includes all Unicode alphanumeric characters (as defined by *str.isalnum()*), as well as the underscore (_).

Matches `[a-zA-Z0-9_]` if the *ASCII* flag is used.

For 8-bit (bytes) patterns:
Matches characters considered alphanumeric in the ASCII character set; this is equivalent to `[a-zA-Z0-9_]`. If the *LOCALE* flag is used, matches characters considered alphanumeric in the current locale and the underscore.

\W

Matches any character which is not a word character. This is the opposite of `\w`. By default, matches non-underscore (_) characters for which *str.isalnum()* returns `False`.

Matches `[^a-zA-Z0-9_]` if the *ASCII* flag is used.

If the *LOCALE* flag is used, matches characters which are neither alphanumeric in the current locale nor the underscore.

\Z

Matches only at the end of the string.

Most of the escape sequences supported by Python string literals are also accepted by the regular expression parser:

```
\a      \b      \f      \n
\N      \r      \t      \u
\U      \v      \x      \\
```

(Note that `\b` is used to represent word boundaries, and means "backspace" only inside character classes.)

`'\u'`, `'\U'`, and `'\N'` escape sequences are only recognized in Unicode (str) patterns. In bytes patterns they are errors. Unknown escapes of ASCII letters are reserved for future use and treated as errors.

Octal escapes are included in a limited form. If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in length.

Changed in version 3.3: The `'\u'` and `'\U'` escape sequences have been added.

Changed in version 3.6: Unknown escapes consisting of `'\'` and an ASCII letter now are errors.

Changed in version 3.8: The `'\N{name}'` escape sequence has been added. As in string literals, it expands to the named Unicode character (e.g. `'\N{EM DASH}'`).

6.2.2 Module Contents

The module defines several functions, constants, and an exception. Some of the functions are simplified versions of the full featured methods for compiled regular expressions. Most non-trivial applications always use the compiled form.

Flags

Changed in version 3.6: Flag constants are now instances of *RegexFlag*, which is a subclass of *enum.IntFlag*.

class re.**RegexFlag**

An *enum.IntFlag* class containing the regex options listed below.

Added in version 3.11: - added to __all__

re.**A**

re.**ASCII**

Make \w, \W, \b, \B, \d, \D, \s and \S perform ASCII-only matching instead of full Unicode matching. This is only meaningful for Unicode (str) patterns, and is ignored for bytes patterns.

Corresponds to the inline flag (?a).

> **Note**
>
> The *U* flag still exists for backward compatibility, but is redundant in Python 3 since matches are Unicode by default for str patterns, and Unicode matching isn't allowed for bytes patterns. *UNICODE* and the inline flag (?u) are similarly redundant.

re.**DEBUG**

Display debug information about compiled expression.

No corresponding inline flag.

re.**I**

re.**IGNORECASE**

Perform case-insensitive matching; expressions like [A-Z] will also match lowercase letters. Full Unicode matching (such as Ü matching ü) also works unless the *ASCII* flag is used to disable non-ASCII matches. The current locale does not change the effect of this flag unless the *LOCALE* flag is also used.

Corresponds to the inline flag (?i).

Note that when the Unicode patterns [a-z] or [A-Z] are used in combination with the *IGNORECASE* flag, they will match the 52 ASCII letters and 4 additional non-ASCII letters: 'İ' (U+0130, Latin capital letter I with dot above), 'ı' (U+0131, Latin small letter dotless i), 'ſ' (U+017F, Latin small letter long s) and 'K' (U+212A, Kelvin sign). If the *ASCII* flag is used, only letters 'a' to 'z' and 'A' to 'Z' are matched.

re.**L**

re.**LOCALE**

Make \w, \W, \b, \B and case-insensitive matching dependent on the current locale. This flag can be used only with bytes patterns.

Corresponds to the inline flag (?L).

> **Warning**
>
> This flag is discouraged; consider Unicode matching instead. The locale mechanism is very unreliable as it only handles one "culture" at a time and only works with 8-bit locales. Unicode matching is enabled by default for Unicode (str) patterns and it is able to handle different locales and languages.

Changed in version 3.6: *LOCALE* can be used only with bytes patterns and is not compatible with *ASCII*.

Changed in version 3.7: Compiled regular expression objects with the *LOCALE* flag no longer depend on the locale at compile time. Only the locale at matching time affects the result of matching.

re.**M**

re.**MULTILINE**

When specified, the pattern character `'^'` matches at the beginning of the string and at the beginning of each line (immediately following each newline); and the pattern character `'$'` matches at the end of the string and at the end of each line (immediately preceding each newline). By default, `'^'` matches only at the beginning of the string, and `'$'` only at the end of the string and immediately before the newline (if any) at the end of the string.

Corresponds to the inline flag `(?m)`.

re.**NOFLAG**

Indicates no flag being applied, the value is `0`. This flag may be used as a default value for a function keyword argument or as a base value that will be conditionally ORed with other flags. Example of use as a default value:

```
def myfunc(text, flag=re.NOFLAG):
    return re.match(text, flag)
```

Added in version 3.11.

re.**S**

re.**DOTALL**

Make the `'.'` special character match any character at all, including a newline; without this flag, `'.'` will match anything *except* a newline.

Corresponds to the inline flag `(?s)`.

re.**U**

re.**UNICODE**

In Python 3, Unicode characters are matched by default for `str` patterns. This flag is therefore redundant with **no effect** and is only kept for backward compatibility.

See *ASCII* to restrict matching to ASCII characters instead.

re.**X**

re.**VERBOSE**

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored, except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. For example, `(? :` and `* ?` are not allowed. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

This means that the two following regular expression objects that match a decimal number are functionally equal:

```
a = re.compile(r"""\d +  # the integral part
                   \.    # the decimal point
                   \d *  # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

Corresponds to the inline flag `(?x)`.

Functions

re.**compile**(*pattern*, *flags=0*)

Compile a regular expression pattern into a *regular expression object*, which can be used for matching using its `match()`, `search()` and other methods, described below.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

The sequence

```
prog = re.compile(pattern)
result = prog.match(string)
```

is equivalent to

```
result = re.match(pattern, string)
```

but using `re.compile()` and saving the resulting regular expression object for reuse is more efficient when the expression will be used several times in a single program.

> **Note**
>
> The compiled versions of the most recent patterns passed to `re.compile()` and the module-level matching functions are cached, so programs that use only a few regular expressions at a time needn't worry about compiling regular expressions.

re.**search**(*pattern*, *string*, *flags=0*)

Scan through *string* looking for the first location where the regular expression *pattern* produces a match, and return a corresponding `Match`. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

re.**match**(*pattern*, *string*, *flags=0*)

If zero or more characters at the beginning of *string* match the regular expression *pattern*, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

Note that even in `MULTILINE` mode, `re.match()` will only match at the beginning of the string and not at the beginning of each line.

If you want to locate a match anywhere in *string*, use `search()` instead (see also *search() vs. match()*).

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

re.**fullmatch**(*pattern*, *string*, *flags=0*)

If the whole *string* matches the regular expression *pattern*, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

Added in version 3.4.

re.**split**(*pattern*, *string*, *maxsplit=0*, *flags=0*)

Split *string* by the occurrences of *pattern*. If capturing parentheses are used in *pattern*, then the text of all groups in the pattern are also returned as part of the resulting list. If *maxsplit* is nonzero, at most *maxsplit* splits occur, and the remainder of the string is returned as the final element of the list.

```
>>> re.split(r'\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split(r'(\W+)', 'Words, words, words.')
['Words', ', ', 'words', ', ', 'words', '.', '']
>>> re.split(r'\W+', 'Words, words, words.', maxsplit=1)
['Words', 'words, words.']
>>> re.split('[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

If there are capturing groups in the separator and it matches at the start of the string, the result will start with an empty string. The same holds for the end of the string:

```
>>> re.split(r'(\W+)', '...words, words...')
['', '...', 'words', ', ', 'words', '...', '']
```

That way, separator components are always found at the same relative indices within the result list.

Adjacent empty matches are not possible, but an empty match can occur immediately after a non-empty match.

```
>>> re.split(r'\b', 'Words, words, words.')
['', 'Words', ', ', 'words', ', ', 'words', '.']
>>> re.split(r'\W*', '...words...')
['', '', 'w', 'o', 'r', 'd', 's', '', '']
>>> re.split(r'(\W*)', '...words...')
['', '...', '', '', 'w', '', 'o', '', 'r', '', 'd', '', 's', '...', '', '', '']
```

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the | operator).

Changed in version 3.1: Added the optional flags argument.

Changed in version 3.7: Added support of splitting on a pattern that could match an empty string.

Deprecated since version 3.13: Passing *maxsplit* and *flags* as positional arguments is deprecated. In future Python versions they will be *keyword-only parameters*.

`re.`**`findall`**(*pattern*, *string*, *flags=0*)

Return all non-overlapping matches of *pattern* in *string*, as a list of strings or tuples. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

The result depends on the number of capturing groups in the pattern. If there are no groups, return a list of strings matching the whole pattern. If there is exactly one group, return a list of strings matching that group. If multiple groups are present, return a list of tuples of strings matching the groups. Non-capturing groups do not affect the form of the result.

```
>>> re.findall(r'\bf[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
>>> re.findall(r'(\w+)=(\d+)', 'set width=20 and height=10')
[('width', '20'), ('height', '10')]
```

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the | operator).

Changed in version 3.7: Non-empty matches can now start just after a previous empty match.

`re.`**`finditer`**(*pattern*, *string*, *flags=0*)

Return an *iterator* yielding `Match` objects over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the | operator).

Changed in version 3.7: Non-empty matches can now start just after a previous empty match.

re.**sub**(*pattern*, *repl*, *string*, *count=0*, *flags=0*)

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes of ASCII letters are reserved for future use and treated as errors. Other unknown escapes such as `\&` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example:

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*\(\s*\):',
...        r'static PyObject*\npy_\1(void)\n{',
...        'def myfunc():')
'static PyObject*\npy_myfunc(void)\n{'
```

If *repl* is a function, it is called for every non-overlapping occurrence of *pattern*. The function takes a single *Match* argument, and returns the replacement string. For example:

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
...
>>> re.sub('-{1,2}', dashrepl, 'pro----gram-files')
'pro--gram files'
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

The pattern may be a string or a *Pattern*.

The optional argument *count* is the maximum number of pattern occurrences to be replaced; *count* must be a non-negative integer. If omitted or zero, all occurrences will be replaced.

Adjacent empty matches are not possible, but an empty match can occur immediately after a non-empty match. As a result, `sub('x*', '-', 'abxd')` returns `'-a-b--d-'` instead of `'-a-b-d-'`.

In string-type *repl* arguments, in addition to the character escapes and backreferences described above, `\g<name>` will use the substring matched by the group named `name`, as defined by the `(?P<name>...)` syntax. `\g<number>` uses the corresponding group number; `\g<2>` is therefore equivalent to `\2`, but isn't ambiguous in a replacement such as `\g<2>0`. `\20` would be interpreted as a reference to group 20, not a reference to group 2 followed by the literal character `'0'`. The backreference `\g<0>` substitutes in the entire substring matched by the RE.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

Changed in version 3.1: Added the optional flags argument.

Changed in version 3.5: Unmatched groups are replaced with an empty string.

Changed in version 3.6: Unknown escapes in *pattern* consisting of `'\'` and an ASCII letter now are errors.

Changed in version 3.7: Unknown escapes in *repl* consisting of `'\'` and an ASCII letter now are errors. An empty match can occur immediately after a non-empty match.

Changed in version 3.12: Group *id* can only contain ASCII digits. In *bytes* replacement strings, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

Deprecated since version 3.13: Passing *count* and *flags* as positional arguments is deprecated. In future Python versions they will be *keyword-only parameters*.

re.**subn**(*pattern*, *repl*, *string*, *count=0*, *flags=0*)

Perform the same operation as *sub()*, but return a tuple `(new_string, number_of_subs_made)`.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

re.**escape**(*pattern*)

Escape special characters in *pattern*. This is useful if you want to match an arbitrary literal string that may have regular expression metacharacters in it. For example:

```
>>> print(re.escape('https://www.python.org'))
https://www\.python\.org

>>> legal_chars = string.ascii_lowercase + string.digits + "!#$%&'*+-.^_`|~:"
>>> print('[%s]+' % re.escape(legal_chars))
[abcdefghijklmnopqrstuvwxyz0123456789!\#\$\%\&\'\*\+\-\.\^_`\|\~:]+

>>> operators = ['+', '-', '*', '/', '**']
>>> print('|'.join(map(re.escape, sorted(operators, reverse=True))))
/|\-|\+|\*\*|\*
```

This function must not be used for the replacement string in *sub()* and *subn()*, only backslashes should be escaped. For example:

```
>>> digits_re = r'\d+'
>>> sample = '/usr/sbin/sendmail - 0 errors, 12 warnings'
>>> print(re.sub(digits_re, digits_re.replace('\\', r'\\'), sample))
/usr/sbin/sendmail - \d+ errors, \d+ warnings
```

Changed in version 3.3: The `'_'` character is no longer escaped.

Changed in version 3.7: Only characters that can have special meaning in a regular expression are escaped. As a result, `'!'`, `'"'`, `'%'`, `"'"`, `','`, `'/'`, `':'`, `';'`, `'<'`, `'='`, `'>'`, `'@'`, and `"`" are no longer escaped.

re.**purge**()

Clear the regular expression cache.

Exceptions

exception re.**PatternError**(*msg*, *pattern=None*, *pos=None*)

Exception raised when a string passed to one of the functions here is not a valid regular expression (for example, it might contain unmatched parentheses) or when some other error occurs during compilation or matching. It is never an error if a string contains no match for a pattern. The `PatternError` instance has the following additional attributes:

msg

The unformatted error message.

pattern

The regular expression pattern.

pos

The index in *pattern* where compilation failed (may be `None`).

lineno

The line corresponding to *pos* (may be `None`).

colno

The column corresponding to *pos* (may be `None`).

Changed in version 3.5: Added additional attributes.

Changed in version 3.13: `PatternError` was originally named `error`; the latter is kept as an alias for backward compatibility.

6.2.3 Regular Expression Objects

class re.**Pattern**

Compiled regular expression object returned by *re.compile()*.

Changed in version 3.9: *re.Pattern* supports `[]` to indicate a Unicode (str) or bytes pattern. See *Generic Alias Type*.

Pattern.**search**(*string*[, *pos*[, *endpos*]])

Scan through *string* looking for the first location where this regular expression produces a match, and return a corresponding *Match*. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional second parameter *pos* gives an index in the string where the search is to start; it defaults to `0`. This is not completely equivalent to slicing the string; the `'^'` pattern character matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter *endpos* limits how far the string will be searched; it will be as if the string is *endpos* characters long, so only the characters from *pos* to `endpos - 1` will be searched for a match. If *endpos* is less than *pos*, no match will be found; otherwise, if *rx* is a compiled regular expression object, `rx.search(string, 0, 50)` is equivalent to `rx.search(string[:50], 0)`.

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")      # Match at index 0
<re.Match object; span=(0, 1), match='d'>
>>> pattern.search("dog", 1)   # No match; search doesn't include the "d"
```

Pattern.**match**(*string*[, *pos*[, *endpos*]])

If zero or more characters at the *beginning* of *string* match this regular expression, return a corresponding *Match*. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")      # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)   # Match as "o" is the 2nd character of "dog".
<re.Match object; span=(1, 2), match='o'>
```

If you want to locate a match anywhere in *string*, use *search()* instead (see also *search() vs. match()*).

Pattern.**fullmatch**(*string*[, *pos*[, *endpos*]])

If the whole *string* matches this regular expression, return a corresponding *Match*. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o[gh]")
>>> pattern.fullmatch("dog")      # No match as "o" is not at the start of "dog
↪".
>>> pattern.fullmatch("ogre")     # No match as not the full string matches.
>>> pattern.fullmatch("doggie", 1, 3)   # Matches within given limits.
<re.Match object; span=(1, 3), match='og'>
```

Added in version 3.4.

Pattern.**split**(*string*, *maxsplit=0*)

Identical to the *split()* function, using the compiled pattern.

Pattern.**findall**(*string*[, *pos*[, *endpos*]])

Similar to the *findall()* function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for *search()*.

Pattern.**finditer**(*string*[, *pos*[, *endpos*]])

Similar to the *finditer()* function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for *search()*.

Pattern.**sub**(*repl*, *string*, *count=0*)

Identical to the *sub()* function, using the compiled pattern.

Pattern.**subn**(*repl*, *string*, *count=0*)

Identical to the *subn()* function, using the compiled pattern.

Pattern.**flags**

The regex matching flags. This is a combination of the flags given to *compile()*, any `(?...)` inline flags in the pattern, and implicit flags such as *UNICODE* if the pattern is a Unicode string.

Pattern.**groups**

The number of capturing groups in the pattern.

Pattern.**groupindex**

A dictionary mapping any symbolic group names defined by `(?P<id>)` to group numbers. The dictionary is empty if no symbolic groups were used in the pattern.

Pattern.**pattern**

The pattern string from which the pattern object was compiled.

Changed in version 3.7: Added support of *copy.copy()* and *copy.deepcopy()*. Compiled regular expression objects are considered atomic.

6.2.4 Match Objects

Match objects always have a boolean value of `True`. Since *match()* and *search()* return `None` when there is no match, you can test whether there was a match with a simple `if` statement:

```
match = re.search(pattern, string)
if match:
    process(match)
```

class re.**Match**

Match object returned by successful `match`es and `search`es.

Changed in version 3.9: *re.Match* supports `[]` to indicate a Unicode (str) or bytes match. See *Generic Alias Type*.

Match.**expand**(*template*)

Return the string obtained by doing backslash substitution on the template string *template*, as done by the *sub()* method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group. The backreference `\g<0>` will be replaced by the entire match.

Changed in version 3.5: Unmatched groups are replaced with an empty string.

Match.**group**([*group1*, ...])

Returns one or more subgroups of the match. If there is a single argument, the result is a single string; if there are multiple arguments, the result is a tuple with one item per argument. Without arguments, *group1* defaults to zero (the whole match is returned). If a *groupN* argument is zero, the corresponding return value is the entire matching string; if it is in the inclusive range [1..99], it is the string matching the corresponding parenthesized group. If a group number is negative or larger than the number of groups defined in the pattern, an *IndexError* exception is raised. If a group is contained in a part of the pattern that did not match, the corresponding result is `None`. If a group is contained in a part of the pattern that matched multiple times, the last match is returned.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)       # The entire match
'Isaac Newton'
>>> m.group(1)       # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)       # The second parenthesized subgroup.
'Newton'
>>> m.group(1, 2)    # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

If the regular expression uses the `(?P<name>...)` syntax, the *groupN* arguments may also be strings identifying groups by their group name. If a string argument is not used as a group name in the pattern, an *IndexError* exception is raised.

A moderately complicated example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Named groups can also be referred to by their index:

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

If a group matches multiple times, only the last match is accessible:

```
>>> m = re.match(r"(..)+", "a1b2c3")  # Matches 3 times.
>>> m.group(1)                        # Returns only the last match.
'c3'
```

`Match.__getitem__`(*g*)

This is identical to `m.group(g)`. This allows easier access to an individual group from a match:

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m[0]       # The entire match
'Isaac Newton'
>>> m[1]       # The first parenthesized subgroup.
'Isaac'
>>> m[2]       # The second parenthesized subgroup.
'Newton'
```

Named groups are supported as well:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Isaac Newton")
>>> m['first_name']
'Isaac'
>>> m['last_name']
'Newton'
```

Added in version 3.6.

`Match.groups`(*default=None*)

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match; it defaults to `None`.

For example:

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

If we make the decimal place and everything after it optional, not all groups might participate in the match. These groups will default to `None` unless the *default* argument is given:

```
>>> m = re.match(r"(\d+)\.?(\d+)?", "24")
>>> m.groups()      # Second group defaults to None.
('24', None)
>>> m.groups('0')   # Now, the second group defaults to '0'.
('24', '0')
```

`Match.`**`groupdict`**`(`*default=None*`)`

Return a dictionary containing all the *named* subgroups of the match, keyed by the subgroup name. The *default* argument is used for groups that did not participate in the match; it defaults to `None`. For example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

`Match.`**`start`**`(`[*group*]`)`

`Match.`**`end`**`(`[*group*]`)`

Return the indices of the start and end of the substring matched by *group*; *group* defaults to zero (meaning the whole matched substring). Return `-1` if *group* exists but did not contribute to the match. For a match object *m*, and a group *g* that did contribute to the match, the substring matched by group *g* (equivalent to `m.group(g)`) is

```
m.string[m.start(g):m.end(g)]
```

Note that `m.start(group)` will equal `m.end(group)` if *group* matched a null string. For example, after `m = re.search('b(c?)', 'cba')`, `m.start(0)` is 1, `m.end(0)` is 2, `m.start(1)` and `m.end(1)` are both 2, and `m.start(2)` raises an *IndexError* exception.

An example that will remove *remove_this* from email addresses:

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

`Match.`**`span`**`(`[*group*]`)`

For a match *m*, return the 2-tuple `(m.start(group), m.end(group))`. Note that if *group* did not contribute to the match, this is `(-1, -1)`. *group* defaults to zero, the entire match.

`Match.`**`pos`**

The value of *pos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string at which the RE engine started looking for a match.

`Match.`**`endpos`**

The value of *endpos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string beyond which the RE engine will not go.

`Match.`**`lastindex`**

The integer index of the last matched capturing group, or `None` if no group was matched at all. For example, the expressions `(a)b`, `((a)(b))`, and `((ab))` will have `lastindex == 1` if applied to the string `'ab'`, while the expression `(a)(b)` will have `lastindex == 2`, if applied to the same string.

`Match.`**`lastgroup`**

The name of the last matched capturing group, or `None` if the group didn't have a name, or if no group was matched at all.

`Match.`**`re`**

The *regular expression object* whose *`match()`* or *`search()`* method produced this match instance.

`Match.`**`string`**

The string passed to *`match()`* or *`search()`*.

Changed in version 3.7: Added support of *`copy.copy()`* and *`copy.deepcopy()`*. Match objects are considered atomic.

6.2.5 Regular Expression Examples

Checking for a Pair

In this example, we'll use the following helper function to display match objects a little more gracefully:

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

Suppose you are writing a poker program where a player's hand is represented as a 5-character string with each character representing a card, "a" for ace, "k" for king, "q" for queen, "j" for jack, "t" for 10, and "2" through "9" representing the card with that value.

To see if a given string is a valid hand, one could do the following:

```
>>> valid = re.compile(r"^[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q"))  # Valid.
"<Match: 'akt5q', groups=()>"
>>> displaymatch(valid.match("akt5e"))  # Invalid.
>>> displaymatch(valid.match("akt"))    # Invalid.
>>> displaymatch(valid.match("727ak"))  # Valid.
"<Match: '727ak', groups=()>"
```

That last hand, `"727ak"`, contained a pair, or two of the same valued cards. To match this with a regular expression, one could use backreferences as such:

```
>>> pair = re.compile(r".*(.).*\1")
>>> displaymatch(pair.match("717ak"))     # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak"))     # No pairs.
>>> displaymatch(pair.match("354aa"))     # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the *`group()`* method of the match object in the following manner:

```
>>> pair = re.compile(r".*(.).*\1")
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    re.match(r".*(.).*\1", "718ak").group(1)
```

(continues on next page)

(continued from previous page)

```
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

Simulating scanf()

Python does not currently have an equivalent to `scanf()`. Regular expressions are generally more powerful, though also more verbose, than `scanf()` format strings. The table below offers some more-or-less equivalent mappings between `scanf()` format tokens and regular expressions.

`scanf()` Token	Regular Expression
`%c`	`.`
`%5c`	`.{5}`
`%d`	`[-+]?\d+`
`%e, %E, %f, %g`	`[-+]?(\d+(\.\d*)?|\.\d+)([eE][-+]?\d+)?`
`%i`	`[-+]?(0[xX][\dA-Fa-f]+|0[0-7]*|\d+)`
`%o`	`[-+]?[0-7]+`
`%s`	`\S+`
`%u`	`\d+`
`%x, %X`	`[-+]?(0[xX])?[\dA-Fa-f]+`

To extract the filename and numbers from a string like

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

you would use a `scanf()` format like

```
%s - %d errors, %d warnings
```

The equivalent regular expression would be

```
(\S+) - (\d+) errors, (\d+) warnings
```

search() vs. match()

Python offers different primitive operations based on regular expressions:

- *`re.match()`* checks for a match only at the beginning of the string
- *`re.search()`* checks for a match anywhere in the string (this is what Perl does by default)
- *`re.fullmatch()`* checks for entire string to be a match

For example:

```
>>> re.match("c", "abcdef")    # No match
>>> re.search("c", "abcdef")   # Match
<re.Match object; span=(2, 3), match='c'>
>>> re.fullmatch("p.*n", "python") # Match
<re.Match object; span=(0, 6), match='python'>
>>> re.fullmatch("r.*n", "python") # No match
```

Regular expressions beginning with `'^'` can be used with *`search()`* to restrict the match at the beginning of the string:

```
>>> re.match("c", "abcdef")    # No match
>>> re.search("^c", "abcdef")  # No match
>>> re.search("^a", "abcdef")  # Match
<re.Match object; span=(0, 1), match='a'>
```

Note however that in *MULTILINE* mode *match()* only matches at the beginning of the string, whereas using *search()* with a regular expression beginning with `'^'` will match at the beginning of each line.

```
>>> re.match("X", "A\nB\nX", re.MULTILINE)  # No match
>>> re.search("^X", "A\nB\nX", re.MULTILINE)  # Match
<re.Match object; span=(4, 5), match='X'>
```

Making a Phonebook

split() splits a string into a list delimited by the passed pattern. The method is invaluable for converting textual data into data structures that can be easily read and modified by Python as demonstrated in the following example that creates a phonebook.

First, here is the input. Normally it may come from a file, here we are using triple-quoted string syntax

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

The entries are separated by one or more newlines. Now we convert the string into a list with each nonempty line having its own entry:

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
'Frank Burger: 925.541.7625 662 South Dogwood Way',
'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finally, split each entry into a list with first name, last name, telephone number, and address. We use the `maxsplit` parameter of *split()* because the address has spaces, our splitting pattern, in it:

```
>>> [re.split(":? ", entry, maxsplit=3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

The `:?` pattern matches the colon after the last name, so that it does not occur in the result list. With a `maxsplit` of `4`, we could separate the house number from the street name:

```
>>> [re.split(":? ", entry, maxsplit=4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

Text Munging

sub() replaces every occurrence of a pattern with a string or the result of a function. This example demonstrates using *sub()* with a function to "munge" text, or randomize the order of all the characters in each word of a sentence except for the first and last characters:

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
...
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlobdk, pslaee reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reoprt yuor asnebces potlmrpy.'
```

Finding all Adverbs

findall() matches *all* occurrences of a pattern, not just the first one as *search()* does. For example, if a writer wanted to find all of the adverbs in some text, they might use *findall()* in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly\b", text)
['carefully', 'quickly']
```

Finding all Adverbs and their Positions

If one wants more information about all matches of a pattern than the matched text, *finditer()* is useful as it provides *Match* objects instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use *finditer()* in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly\b", text):
...     print('%02d-%02d: %s' % (m.start(), m.end(), m.group(0)))
07-16: carefully
40-47: quickly
```

Raw String Notation

Raw string notation (`r"text"`) keeps regular expressions sane. Without it, every backslash (`'\'`) in a regular expression would have to be prefixed with another one to escape it. For example, the two following lines of code are functionally identical:

```
>>> re.match(r"\W(.)\1\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
>>> re.match("\\W(.)\\1\\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
```

When one wants to match a literal backslash, it must be escaped in the regular expression. With raw string notation, this means `r"\\"`. Without raw string notation, one must use `"\\\\"`, making the following lines of code functionally identical:

```
>>> re.match(r"\\", r"\\")
<re.Match object; span=(0, 1), match='\\'>
>>> re.match("\\\\", r"\\")
<re.Match object; span=(0, 1), match='\\'>
```

Writing a Tokenizer

A tokenizer or scanner analyzes a string to categorize groups of characters. This is a useful first step in writing a compiler or interpreter.

The text categories are specified with regular expressions. The technique is to combine those into a single master regular expression and to loop over successive matches:

```
from typing import NamedTuple
import re

class Token(NamedTuple):
    type: str
    value: str
    line: int
    column: int

def tokenize(code):
    keywords = {'IF', 'THEN', 'ENDIF', 'FOR', 'NEXT', 'GOSUB', 'RETURN'}
    token_specification = [
        ('NUMBER',   r'\d+(\.\d*)?'),  # Integer or decimal number
        ('ASSIGN',   r':='),           # Assignment operator
        ('END',      r';'),            # Statement terminator
        ('ID',       r'[A-Za-z]+'),    # Identifiers
        ('OP',       r'[+\-*/]'),      # Arithmetic operators
        ('NEWLINE',  r'\n'),           # Line endings
        ('SKIP',     r'[ \t]+'),       # Skip over spaces and tabs
        ('MISMATCH', r'.'),            # Any other character
    ]
    tok_regex = '|'.join('(?P<%s>%s)' % pair for pair in token_specification)
    line_num = 1
    line_start = 0
    for mo in re.finditer(tok_regex, code):
        kind = mo.lastgroup
        value = mo.group()
        column = mo.start() - line_start
        if kind == 'NUMBER':
            value = float(value) if '.' in value else int(value)
        elif kind == 'ID' and value in keywords:
            kind = value
        elif kind == 'NEWLINE':
            line_start = mo.end()
            line_num += 1
            continue
        elif kind == 'SKIP':
            continue
        elif kind == 'MISMATCH':
            raise RuntimeError(f'{value!r} unexpected on line {line_num}')
        yield Token(kind, value, line_num, column)

statements = '''
    IF quantity THEN
        total := total + price * quantity;
        tax := price * 0.05;
    ENDIF;
'''

for token in tokenize(statements):
    print(token)
```

The tokenizer produces the following output:

```
Token(type='IF', value='IF', line=2, column=4)
Token(type='ID', value='quantity', line=2, column=7)
Token(type='THEN', value='THEN', line=2, column=16)
Token(type='ID', value='total', line=3, column=8)
Token(type='ASSIGN', value=':=', line=3, column=14)
Token(type='ID', value='total', line=3, column=17)
Token(type='OP', value='+', line=3, column=23)
Token(type='ID', value='price', line=3, column=25)
Token(type='OP', value='*', line=3, column=31)
Token(type='ID', value='quantity', line=3, column=33)
Token(type='END', value=';', line=3, column=41)
Token(type='ID', value='tax', line=4, column=8)
Token(type='ASSIGN', value=':=', line=4, column=12)
Token(type='ID', value='price', line=4, column=15)
Token(type='OP', value='*', line=4, column=21)
Token(type='NUMBER', value=0.05, line=4, column=23)
Token(type='END', value=';', line=4, column=27)
Token(type='ENDIF', value='ENDIF', line=5, column=4)
Token(type='END', value=';', line=5, column=9)
```

6.3 `difflib` — Helpers for computing deltas

Source code: Lib/difflib.py

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce information about file differences in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the *filecmp* module.

class difflib.**SequenceMatcher**

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name "gestalt pattern matching." The idea is to find the longest contiguous matching subsequence that contains no "junk" elements; these "junk" elements are ones that are uninteresting in some sense, such as blank lines or whitespace. (Handling junk is an extension to the Ratcliff and Obershelp algorithm.) The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that "look right" to people.

Timing: The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. *SequenceMatcher* is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

Automatic junk heuristic: *SequenceMatcher* supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as "popular" and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the `autojunk` argument to `False` when creating the *SequenceMatcher*.

Changed in version 3.2: Added the *autojunk* parameter.

class difflib.**Differ**

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses *SequenceMatcher* both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a *Differ* delta begins with a two-letter code:

Code	Meaning
`'- '`	line unique to sequence 1
`'+ '`	line unique to sequence 2
`'  '`	line common to both sequences
`'? '`	line not present in either input sequence

Lines beginning with '?' attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain whitespace characters, such as spaces, tabs or line breaks.

class difflib.**HtmlDiff**

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is:

__init__(*tabsize=8*, *wrapcolumn=None*, *linejunk=None*, *charjunk=IS_CHARACTER_JUNK*)

Initializes instance of *HtmlDiff*.

tabsize is an optional keyword argument to specify tab stop spacing and defaults to `8`.

wrapcolumn is an optional keyword to specify column number where lines are broken and wrapped, defaults to `None` where lines are not wrapped.

linejunk and *charjunk* are optional keyword arguments passed into *ndiff()* (used by *HtmlDiff* to generate the side by side HTML differences). See *ndiff()* documentation for argument default values and descriptions.

The following methods are public:

make_file(*fromlines*, *tolines*, *fromdesc=''*, *todesc=''*, *context=False*, *numlines=5*, ***, *charset='utf-8'*)

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

fromdesc and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

context and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to `5`. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight when using the "next" hyperlinks (setting to zero would cause the "next" hyperlinks to place the next difference highlight at the top of the browser without any leading context).

> **Note**
>
> *fromdesc* and *todesc* are interpreted as unescaped HTML and should be properly escaped while receiving input from untrusted sources.

Changed in version 3.5: *charset* keyword-only argument was added. The default charset of HTML document changed from `'ISO-8859-1'` to `'utf-8'`.

make_table(*fromlines*, *tolines*, *fromdesc=''*, *todesc=''*, *context=False*, *numlines=5*)

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the *make_file()* method.

difflib.**context_diff**(*a*, *b*, *fromfile=''*, *tofile=''*, *fromfiledate=''*, *tofiledate=''*, *n=3*, *lineterm='\n'*)

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `""` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> import sys
>>> from difflib import *
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(context_diff(s1, s2, fromfile='before.py',
...                       tofile='after.py'))
*** before.py
--- after.py
***************
*** 1,4 ****
! bacon
! eggs
! ham
  guido
--- 1,4 ----
! python
! eggy
! hamster
  guido
```

See *A command-line interface to difflib* for a more detailed example.

difflib.**get_close_matches**(*word*, *possibilities*, *n=3*, *cutoff=0.6*)

Return a list of the best "good enough" matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default `3`) is the maximum number of close matches to return; *n* must be greater than `0`.

Optional argument *cutoff* (default `0.6`) is a float in the range [0, 1]. Possibilities that don't score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('pineapple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

difflib.**ndiff**(*a*, *b*, *linejunk=None*, *charjunk=IS_CHARACTER_JUNK*)

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are filtering functions (or None):

linejunk: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is None. There is also a module-level function *IS_LINE_JUNK()*, which filters out lines without visible characters, except for at most one pound character ('#') – however the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than using this function.

charjunk: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function *IS_CHARACTER_JUNK()*, which filters out whitespace characters (a blank or tab; it's a bad idea to include newline in this!).

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> print(''.join(diff), end="")
- one
?  ^
+ ore
?  ^
- two
- three
?  -
+ tree
+ emu
```

difflib.**restore**(*sequence*, *which*)

Return one of the two sequences that generated a delta.

Given a *sequence* produced by *Differ.compare()* or *ndiff()*, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

Example:

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print(''.join(restore(diff, 1)), end="")
one
two
three
>>> print(''.join(restore(diff, 2)), end="")
ore
tree
emu
```

difflib.**unified_diff**(*a*, *b*, *fromfile=''*, *tofile=''*, *fromfiledate=''*, *tofiledate=''*, *n=3*, *lineterm='\n'*)

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with ---, +++, or @@) are created with a trailing newline. This is helpful so that inputs created from *io.IOBase.readlines()* result in diffs that are suitable for use with *io.IOBase.writelines()* since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to "" so that the output will be uniformly newline free.

The unified diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(unified_diff(s1, s2, fromfile='before.py', tofile=
↪'after.py'))
--- before.py
+++ after.py
@@ -1,4 +1,4 @@
-bacon
-eggs
-ham
+python
+eggy
+hamster
 guido
```

See *A command-line interface to difflib* for a more detailed example.

`difflib.`**`diff_bytes`**(*dfunc*, *a*, *b*, *fromfile=b''*, *tofile=b''*, *fromfiledate=b''*, *tofiledate=b''*, *n=3*, *lineterm=b'\n'*)

Compare *a* and *b* (lists of bytes objects) using *dfunc*; yield a sequence of delta lines (also bytes) in the format returned by *dfunc*. *dfunc* must be a callable, typically either `unified_diff()` or `context_diff()`.

Allows you to compare data with unknown or inconsistent encoding. All inputs except *n* must be bytes objects, not str. Works by losslessly converting all inputs (except *n*) to str, and calling `dfunc(a, b, fromfile, tofile, fromfiledate, tofiledate, n, lineterm)`. The output of *dfunc* is then converted back to bytes, so the delta lines that you receive have the same unknown/inconsistent encodings as *a* and *b*.

Added in version 3.5.

`difflib.`**`IS_LINE_JUNK`**(*line*)

Return `True` for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single `'#'`, otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` in older versions.

`difflib.`**`IS_CHARACTER_JUNK`**(*ch*)

Return `True` for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

Pattern Matching: The Gestalt Approach
Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in Dr. Dobb's Journal in July, 1988.

6.3.1 SequenceMatcher Objects

The `SequenceMatcher` class has this constructor:

`class` `difflib.`**`SequenceMatcher`**(*isjunk=None*, *a=''*, *b=''*, *autojunk=True*)

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is "junk" and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: False`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you're comparing lines as sequences of characters, and don't want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be *hashable*.

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

Changed in version 3.2: Added the *autojunk* parameter.

SequenceMatcher objects get three data attributes: *bjunk* is the set of elements of *b* for which *isjunk* is `True`; *bpopular* is the set of non-junk elements considered popular by the heuristic (if it is not disabled); *b2j* is a dict mapping the remaining elements of *b* to a list of positions where they occur. All three are reset whenever *b* is reset with `set_seqs()` or `set_seq2()`.

Added in version 3.2: The *bjunk* and *bpopular* attributes.

`SequenceMatcher` objects have the following methods:

set_seqs(*a*, *b*)

Set the two sequences to be compared.

`SequenceMatcher` computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use `set_seq2()` to set the commonly used sequence once and call `set_seq1()` repeatedly, once for each of the other sequences.

set_seq1(*a*)

Set the first sequence to be compared. The second sequence to be compared is not changed.

set_seq2(*b*)

Set the second sequence to be compared. The first sequence to be compared is not changed.

find_longest_match(*alo=0*, *ahi=None*, *blo=0*, *bhi=None*)

Find longest matching block in `a[alo:ahi]` and `b[blo:bhi]`.

If *isjunk* was omitted or `None`, `find_longest_match()` returns `(i, j, k)` such that `a[i:i+k]` is equal to `b[j:j+k]`, where `alo <= i <= i+k <= ahi` and `blo <= j <= j+k <= bhi`. For all `(i', j', k')` meeting those conditions, the additional conditions `k >= k'`, `i <= i'`, and if `i == i'`, `j <= j'` are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents `' abcd'` from matching the `' abcd'` at the tail end of the second sequence directly. Instead only the `'abcd'` can match, and matches the leftmost `'abcd'` in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns `(alo, blo, 0)`.

This method returns a *named tuple* `Match(a, b, size)`.

Changed in version 3.9: Added default arguments.

get_matching_blocks()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form `(i, j, n)`, and means that `a[i:i+n] == b[j:j+n]`. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value `(len(a), len(b), 0)`. It is the only triple with `n == 0`. If `(i, j, n)` and `(i', j', n')` are adjacent triples in the list, and the second is not the last triple in the list, then `i+n < i'` or `j+n < j'`; in other words, adjacent triples always describe non-adjacent equal blocks.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

get_opcodes()

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form `(tag, i1, i2, j1, j2)`. The first tuple has `i1 == j1 == 0`, and remaining tuples have *i1* equal to the *i2* from the preceding tuple, and, likewise, *j1* equal to the previous *j2*.

The *tag* values are strings, with these meanings:

Value	Meaning
`'replace'`	`a[i1:i2]` should be replaced by `b[j1:j2]`.
`'delete'`	`a[i1:i2]` should be deleted. Note that `j1 == j2` in this case.
`'insert'`	`b[j1:j2]` should be inserted at `a[i1:i1]`. Note that `i1 == i2` in this case.
`'equal'`	`a[i1:i2] == b[j1:j2]` (the sub-sequences are equal).

For example:

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print('{:7}   a[{}:{}] --> b[{}:{}] {!r:>8} --> {!r}'.format(
...         tag, i1, i2, j1, j2, a[i1:i2], b[j1:j2]))
delete    a[0:1] --> b[0:0]      'q' --> ''
equal     a[1:3] --> b[0:2]     'ab' --> 'ab'
replace   a[3:4] --> b[2:3]      'x' --> 'y'
equal     a[4:6] --> b[3:5]     'cd' --> 'cd'
insert    a[6:6] --> b[5:6]       '' --> 'f'
```

get_grouped_opcodes(*n=3*)

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by *get_opcodes()*, this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as *get_opcodes()*.

ratio()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is 2.0*M / T. Note that this is `1.0` if the sequences are identical, and `0.0` if they have nothing in common.

This is expensive to compute if *get_matching_blocks()* or *get_opcodes()* hasn't already been called, in which case you may want to try *quick_ratio()* or *real_quick_ratio()* first to get an upper bound.

> **Note**
>
> Caution: The result of a *ratio()* call may depend on the order of the arguments. For instance:
>
> ```
> >>> SequenceMatcher(None, 'tide', 'diet').ratio()
> 0.25
> >>> SequenceMatcher(None, 'diet', 'tide').ratio()
> 0.5
> ```

quick_ratio()

Return an upper bound on *ratio()* relatively quickly.

real_quick_ratio()

Return an upper bound on *ratio()* very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although *quick_ratio()* and *real_quick_ratio()* are always at least as large as *ratio()*:

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

6.3.2 SequenceMatcher Examples

This example compares two strings, considering blanks to be "junk":

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                     "private Thread currentThread;",
...                     "private volatile Thread currentThread;")
```

ratio() returns a float in [0, 1], measuring the similarity of the sequences. As a rule of thumb, a *ratio()* value over 0.6 means the sequences are close matches:

```
>>> print(round(s.ratio(), 3))
0.866
```

If you're only interested in where the sequences match, *get_matching_blocks()* is handy:

```
>>> for block in s.get_matching_blocks():
...     print("a[%d] and b[%d] match for %d elements" % block)
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by *get_matching_blocks()* is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is `0`.

If you want to know how to change the first sequence into the second, use *get_opcodes()*:

```
>>> for opcode in s.get_opcodes():
...     print("%6s a[%d:%d] b[%d:%d]" % opcode)
 equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
 equal a[8:29] b[17:38]
```

- The *get_close_matches()* function in this module which shows how simple code building on *SequenceMatcher* can be used to do useful work.
- Simple version control recipe for a small application built with *SequenceMatcher*.

6.3.3 Differ Objects

Note that *Differ*-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The *Differ* class has this constructor:

class difflib.**Differ**(*linejunk=None*, *charjunk=None*)

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or `None`):

linejunk: A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

charjunk: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

These junk-filtering functions speed up matching to find differences and do not cause any differing lines or characters to be ignored. Read the description of the *find_longest_match()* method's *isjunk* parameter for an explanation.

Differ objects are used (deltas generated) via a single method:

compare(*a*, *b*)

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the *readlines()* method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the *writelines()* method of a file-like object.

6.3.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the *readlines()* method of file-like objects):

```
>>> text1 = '''  1. Beautiful is better than ugly.
...   2. Explicit is better than implicit.
...   3. Simple is better than complex.
...   4. Complex is better than complicated.
... '''.splitlines(keepends=True)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = '''  1. Beautiful is better than ugly.
...   3.   Simple is better than complex.
...   4. Complicated is better than complex.
...   5. Flat is better than nested.
... '''.splitlines(keepends=True)
```

Next we instantiate a Differ object:

```
>>> d = Differ()
```

Note that when instantiating a *Differ* object we may pass functions to filter out line and character "junk." See the *Differ()* constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

`result` is a list of strings, so let's pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
['    1. Beautiful is better than ugly.\n',
 '-   2. Explicit is better than implicit.\n',
 '-   3. Simple is better than complex.\n',
 '+   3.   Simple is better than complex.\n',
 '?     ++\n',
 '-   4. Complex is better than complicated.\n',
 '?            ^                     ---- ^\n',
 '+   4. Complicated is better than complex.\n',
 '?           ++++ ^                     ^\n',
 '+   5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
    1. Beautiful is better than ugly.
-   2. Explicit is better than implicit.
-   3. Simple is better than complex.
+   3.   Simple is better than complex.
?     ++
-   4. Complex is better than complicated.
?            ^                     ---- ^
+   4. Complicated is better than complex.
?           ++++ ^                     ^
+   5. Flat is better than nested.
```

6.3.5 A command-line interface to difflib

This example shows how to use difflib to create a `diff`-like utility.

```
""" Command line interface to difflib.py providing diffs in four formats:

* ndiff:    lists every line and highlights interline changes.
* context:  highlights clusters of changes in a before/after format.
* unified:  highlights clusters of changes in an inline format.
* html:     generates side by side comparison with change highlights.

"""

import sys, os, difflib, argparse
from datetime import datetime, timezone

def file_mtime(path):
    t = datetime.fromtimestamp(os.stat(path).st_mtime,
                               timezone.utc)
```

(continues on next page)

(continued from previous page)

```
    return t.astimezone().isoformat()

def main():

    parser = argparse.ArgumentParser()
    parser.add_argument('-c', action='store_true', default=False,
                        help='Produce a context format diff (default)')
    parser.add_argument('-u', action='store_true', default=False,
                        help='Produce a unified format diff')
    parser.add_argument('-m', action='store_true', default=False,
                        help='Produce HTML side by side diff '
                             '(can use -c and -l in conjunction)')
    parser.add_argument('-n', action='store_true', default=False,
                        help='Produce a ndiff format diff')
    parser.add_argument('-l', '--lines', type=int, default=3,
                        help='Set number of context lines (default 3)')
    parser.add_argument('fromfile')
    parser.add_argument('tofile')
    options = parser.parse_args()

    n = options.lines
    fromfile = options.fromfile
    tofile = options.tofile

    fromdate = file_mtime(fromfile)
    todate = file_mtime(tofile)
    with open(fromfile) as ff:
        fromlines = ff.readlines()
    with open(tofile) as tf:
        tolines = tf.readlines()

    if options.u:
        diff = difflib.unified_diff(fromlines, tolines, fromfile, tofile, fromdate,
↪ todate, n=n)
    elif options.n:
        diff = difflib.ndiff(fromlines, tolines)
    elif options.m:
        diff = difflib.HtmlDiff().make_file(fromlines,tolines,fromfile,tofile,
↪context=options.c,numlines=n)
    else:
        diff = difflib.context_diff(fromlines, tolines, fromfile, tofile, fromdate,
↪ todate, n=n)

    sys.stdout.writelines(diff)

if __name__ == '__main__':
    main()
```

6.3.6 ndiff example

This example shows how to use *difflib.ndiff()*.

```
"""ndiff [-q] file1 file2
    or
ndiff (-r1 | -r2) < ndiff_output > file1_or_file2
```

(continues on next page)

(continued from previous page)

```
Print a human-friendly file difference report to stdout.  Both inter-
and intra-line differences are noted.  In the second form, recreate file1
(-r1) or file2 (-r2) on stdout, from an ndiff report on stdin.

In the first form, if -q ("quiet") is not specified, the first two lines
of output are

-: file1
+: file2

Each remaining line begins with a two-letter code:

    "- "    line unique to file1
    "+ "    line unique to file2
    "  "    line common to both files
    "? "    line not present in either input file

Lines beginning with "? " attempt to guide the eye to intraline
differences, and were not present in either input file.  These lines can be
confusing if the source files contain tab characters.

The first file can be recovered by retaining only lines that begin with
"  " or "- ", and deleting those 2-character prefixes; use ndiff with -r1.

The second file can be recovered similarly, but by retaining only "  " and
"+ " lines; use ndiff with -r2; or, on Unix, the second file can be
recovered by piping the output through

    sed -n '/^[+ ] /s/^..//p'
"""

6.4 `textwrap` — Text wrapping and filling

Source code: Lib/textwrap.py

The `textwrap` module provides some convenience functions, as well as `TextWrapper`, the class that does all the work. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of `TextWrapper` for efficiency.

`textwrap.`**`wrap`**(*text*, *width=70*, ***, *initial_indent=''*, *subsequent_indent=''*, *expand_tabs=True*, *replace_whitespace=True*, *fix_sentence_endings=False*, *break_long_words=True*, *drop_whitespace=True*, *break_on_hyphens=True*, *tabsize=8*, *max_lines=None*, *placeholder=' [...]'*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below.

See the `TextWrapper.wrap()` method for additional details on how `wrap()` behaves.

`textwrap.`**`fill`**(*text*, *width=70*, ***, *initial_indent=''*, *subsequent_indent=''*, *expand_tabs=True*, *replace_whitespace=True*, *fix_sentence_endings=False*, *break_long_words=True*, *drop_whitespace=True*, *break_on_hyphens=True*, *tabsize=8*, *max_lines=None*, *placeholder=' [...]'*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph. `fill()` is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, `fill()` accepts exactly the same keyword arguments as `wrap()`.

`textwrap.`**`shorten`**(*text*, *width*, ***, *fix_sentence_endings=False*, *break_long_words=True*, *break_on_hyphens=True*, *placeholder=' [...]'*)

Collapse and truncate the given *text* to fit in the given *width*.

First the whitespace in *text* is collapsed (all whitespace is replaced by single spaces). If the result fits in the *width*, it is returned. Otherwise, enough words are dropped from the end so that the remaining words plus the *placeholder* fit within *width*:

```
>>> textwrap.shorten("Hello  world!", width=12)
'Hello world!'
>>> textwrap.shorten("Hello  world!", width=11)
'Hello [...]'
>>> textwrap.shorten("Hello world", width=10, placeholder="...")
'Hello...'
```

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below. Note that the whitespace is collapsed before the text is passed to the `TextWrapper` `fill()` function, so changing the value of `tabsize`, `expand_tabs`, `drop_whitespace`, and `replace_whitespace` will have no effect.

Added in version 3.4.

`textwrap.`**`dedent`**(*text*)

Remove any common leading whitespace from every line in *text*.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines `"  hello"` and `"\thello"` are considered to have no common leading whitespace.

Lines containing only whitespace are ignored in the input and normalized to a single newline character in the output.

For example:

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
    hello
      world
    '''
    print(repr(s))          # prints '    hello\n      world\n    '
    print(repr(dedent(s)))  # prints 'hello\n  world\n'
```

textwrap.**indent**(*text*, *prefix*, *predicate=None*)

Add *prefix* to the beginning of selected lines in *text*.

Lines are separated by calling `text.splitlines(True)`.

By default, *prefix* is added to all lines that do not consist solely of whitespace (including any line endings).

For example:

```
>>> s = 'hello\n\n \nworld'
>>> indent(s, '  ')
'  hello\n\n \n  world'
```

The optional *predicate* argument can be used to control which lines are indented. For example, it is easy to add *prefix* to even empty and whitespace-only lines:

```
>>> print(indent(s, '+ ', lambda line: True))
+ hello
+
+
+ world
```

Added in version 3.3.

wrap(), *fill()* and *shorten()* work by creating a *TextWrapper* instance and calling a single method on it. That instance is not reused, so for applications that process many text strings using *wrap()* and/or *fill()*, it may be more efficient to create your own *TextWrapper* object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless *TextWrapper.break_long_words* is set to false.

class textwrap.**TextWrapper**(***kwargs*)

The *TextWrapper* constructor accepts a number of optional keyword arguments. Each keyword argument corresponds to an instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can reuse the same *TextWrapper* object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The *TextWrapper* instance attributes (and keyword arguments to the constructor) are as follows:

width

(default: `70`) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than *width*, *TextWrapper* guarantees that no output line will be longer than *width* characters.

expand_tabs

(default: `True`) If true, then all tab characters in *text* will be expanded to spaces using the *expandtabs()* method of *text*.

tabsize

(default: `8`) If *expand_tabs* is true, then all tab characters in *text* will be expanded to zero or more spaces, depending on the current column and the given tab size.

Added in version 3.3.

replace_whitespace

(default: `True`) If true, after tab expansion but before wrapping, the *wrap()* method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

> **Note**
>
> If *expand_tabs* is false and *replace_whitespace* is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

> **Note**
>
> If *replace_whitespace* is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using *str.splitlines()* or similar) which are wrapped separately.

drop_whitespace

(default: `True`) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

initial_indent

(default: `''`) String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

subsequent_indent

(default: `''`) String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

fix_sentence_endings

(default: `False`) If true, *TextWrapper* attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of `'.'`, `'!'`, or `'?'`, possibly followed by one of `'"'` or `"'"`, followed by a space. One problem with this algorithm is that it is unable to detect the difference between "Dr." in

```
[...] Dr. Frankenstein's monster [...]
```

and "Spot." in

```
[...] See Spot. See Spot run [...]
```

fix_sentence_endings is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of "lowercase letter", and a convention of using two spaces after a period to separate sentences on the same line, it is specific to English-language texts.

break_long_words

(default: `True`) If true, then words longer than *width* will be broken in order to ensure that no lines are longer than *width*. If it is false, long words will not be broken, and some lines may be longer than *width*. (Long words will be put on a line by themselves, in order to minimize the amount by which *width* is exceeded.)

break_on_hyphens

(default: `True`) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set *break_long_words* to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

max_lines

(default: `None`) If not `None`, then the output will contain at most *max_lines* lines, with *placeholder* appearing at the end of the output.

Added in version 3.4.

placeholder

(default: `' [...]'`) String that will appear at the end of the output text if it has been truncated.

Added in version 3.4.

TextWrapper also provides some public methods, analogous to the module-level convenience functions:

wrap(*text*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. All wrapping options are taken from instance attributes of the *TextWrapper* instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

fill(*text*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

6.5 `unicodedata` — Unicode Database

This module provides access to the Unicode Character Database (UCD) which defines character properties for all Unicode characters. The data contained in this database is compiled from the UCD version 15.1.0.

The module uses the same names and symbols as defined by Unicode Standard Annex #44, "Unicode Character Database". It defines the following functions:

`unicodedata.`**lookup**(*name*)

Look up character by name. If a character with the given name is found, return the corresponding character. If not found, *KeyError* is raised.

Changed in version 3.3: Support for name aliases[1] and named sequences[2] has been added.

`unicodedata.`**name**(*chr*[, *default*])

Returns the name assigned to the character *chr* as a string. If no name is defined, *default* is returned, or, if not given, *ValueError* is raised.

`unicodedata.`**decimal**(*chr*[, *default*])

Returns the decimal value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

`unicodedata.`**digit**(*chr*[, *default*])

Returns the digit value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

[1] https://www.unicode.org/Public/15.1.0/ucd/NameAliases.txt
[2] https://www.unicode.org/Public/15.1.0/ucd/NamedSequences.txt

unicodedata.**numeric**(*chr*[, *default*])

Returns the numeric value assigned to the character *chr* as float. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

unicodedata.**category**(*chr*)

Returns the general category assigned to the character *chr* as string.

unicodedata.**bidirectional**(*chr*)

Returns the bidirectional class assigned to the character *chr* as string. If no such value is defined, an empty string is returned.

unicodedata.**combining**(*chr*)

Returns the canonical combining class assigned to the character *chr* as integer. Returns `0` if no combining class is defined.

unicodedata.**east_asian_width**(*chr*)

Returns the east asian width assigned to the character *chr* as string.

unicodedata.**mirrored**(*chr*)

Returns the mirrored property assigned to the character *chr* as integer. Returns `1` if the character has been identified as a "mirrored" character in bidirectional text, `0` otherwise.

unicodedata.**decomposition**(*chr*)

Returns the character decomposition mapping assigned to the character *chr* as string. An empty string is returned in case no such mapping is defined.

unicodedata.**normalize**(*form*, *unistr*)

Return the normal form *form* for the Unicode string *unistr*. Valid values for *form* are 'NFC', 'NFKC', 'NFD', and 'NFKD'.

The Unicode standard defines various normalization forms of a Unicode string, based on the definition of canonical equivalence and compatibility equivalence. In Unicode, several characters can be expressed in various way. For example, the character U+00C7 (LATIN CAPITAL LETTER C WITH CEDILLA) can also be expressed as the sequence U+0043 (LATIN CAPITAL LETTER C) U+0327 (COMBINING CEDILLA).

For each character, there are two normal forms: normal form C and normal form D. Normal form D (NFD) is also known as canonical decomposition, and translates each character into its decomposed form. Normal form C (NFC) first applies a canonical decomposition, then composes pre-combined characters again.

In addition to these two forms, there are two additional normal forms based on compatibility equivalence. In Unicode, certain characters are supported which normally would be unified with other characters. For example, U+2160 (ROMAN NUMERAL ONE) is really the same thing as U+0049 (LATIN CAPITAL LETTER I). However, it is supported in Unicode for compatibility with existing character sets (e.g. gb2312).

The normal form KD (NFKD) will apply the compatibility decomposition, i.e. replace all compatibility characters with their equivalents. The normal form KC (NFKC) first applies the compatibility decomposition, followed by the canonical composition.

Even if two unicode strings are normalized and look the same to a human reader, if one has combining characters and the other doesn't, they may not compare equal.

unicodedata.**is_normalized**(*form*, *unistr*)

Return whether the Unicode string *unistr* is in the normal form *form*. Valid values for *form* are 'NFC', 'NFKC', 'NFD', and 'NFKD'.

Added in version 3.8.

In addition, the module exposes the following constant:

unicodedata.**unidata_version**

The version of the Unicode database used in this module.

unicodedata.**ucd_3_2_0**

This is an object that has the same methods as the entire module, but uses the Unicode database version 3.2 instead, for applications that require this specific version of the Unicode database (such as IDNA).

Examples:

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
'{'
>>> unicodedata.name('/')
'SOLIDUS'
>>> unicodedata.decimal('9')
9
>>> unicodedata.decimal('a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category('A')  # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional('\u0660') # 'A'rabic, 'N'umber
'AN'
```

6.6 stringprep — Internet String Preparation

Source code: Lib/stringprep.py

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for "equality". Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of "printable" characters.

RFC 3454 defines a procedure for "preparing" Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the stringprep procedure are part of the profile. One example of a stringprep profile is nameprep, which is used for internationalized domain names.

The module *stringprep* only exposes the tables from RFC 3454. As these tables would be very large to represent as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the mkstringprep.py utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC: sets and mappings. For a set, *stringprep* provides the "characteristic function", i.e. a function that returns True if the parameter is part of the set. For mappings, it provides the mapping function: given the key, it returns the associated value. Below is a list of all functions available in the module.

stringprep.**in_table_a1**(*code*)

Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

stringprep.**in_table_b1**(*code*)

Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

stringprep.**map_table_b2**(*code*)

Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

stringprep.**map_table_b3**(*code*)

Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

stringprep.**in_table_c11**(*code*)
: Determine whether *code* is in tableC.1.1 (ASCII space characters).

stringprep.**in_table_c12**(*code*)
: Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

stringprep.**in_table_c11_c12**(*code*)
: Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

stringprep.**in_table_c21**(*code*)
: Determine whether *code* is in tableC.2.1 (ASCII control characters).

stringprep.**in_table_c22**(*code*)
: Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

stringprep.**in_table_c21_c22**(*code*)
: Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

stringprep.**in_table_c3**(*code*)
: Determine whether *code* is in tableC.3 (Private use).

stringprep.**in_table_c4**(*code*)
: Determine whether *code* is in tableC.4 (Non-character code points).

stringprep.**in_table_c5**(*code*)
: Determine whether *code* is in tableC.5 (Surrogate codes).

stringprep.**in_table_c6**(*code*)
: Determine whether *code* is in tableC.6 (Inappropriate for plain text).

stringprep.**in_table_c7**(*code*)
: Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

stringprep.**in_table_c8**(*code*)
: Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

stringprep.**in_table_c9**(*code*)
: Determine whether *code* is in tableC.9 (Tagging characters).

stringprep.**in_table_d1**(*code*)
: Determine whether *code* is in tableD.1 (Characters with bidirectional property “R” or “AL”).

stringprep.**in_table_d2**(*code*)
: Determine whether *code* is in tableD.2 (Characters with bidirectional property “L”).

6.7 `readline` — GNU readline interface

The *readline* module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the *rlcompleter* module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the built-in *input()* function.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See Readline Init File in the GNU Readline manual for information about the format and allowable constructs of that file, and the capabilities of the Readline library in general.

Availability: not Android, not iOS, not WASI.

This module is not supported on *mobile platforms* or *WebAssembly platforms*.

Note

The underlying Readline library API may be implemented by the `editline` (`libedit`) library instead of GNU readline. On macOS the *`readline`* module detects which library is being used at run time.

The configuration file for `editline` is different from that of GNU readline. If you programmatically load configuration strings you can use *`backend`* to determine which library is being used.

If you use `editline`/`libedit` readline emulation on macOS, the initialization file located in your home directory is named `.editrc`. For example, the following content in `~/.editrc` will turn ON *vi* keybindings and TAB completion:

```
python:bind -v
python:bind ^I rl_complete
```

Also note that different libraries may use different history file formats. When switching the underlying library, existing history files may become unusable.

`readline.`**`backend`**

The name of the underlying Readline library being used, either `"readline"` or `"editline"`.

Added in version 3.13.

6.7.1 Init file

The following functions relate to the init file and user configuration:

`readline.`**`parse_and_bind`**(*string*)

Execute the init line provided in the *string* argument. This calls `rl_parse_and_bind()` in the underlying library.

`readline.`**`read_init_file`**([*filename*])

Execute a readline initialization file. The default filename is the last filename used. This calls `rl_read_init_file()` in the underlying library.

6.7.2 Line buffer

The following functions operate on the line buffer:

`readline.`**`get_line_buffer`**()

Return the current contents of the line buffer (`rl_line_buffer` in the underlying library).

`readline.`**`insert_text`**(*string*)

Insert text into the line buffer at the cursor position. This calls `rl_insert_text()` in the underlying library, but ignores the return value.

`readline.`**`redisplay`**()

Change what's displayed on the screen to reflect the current contents of the line buffer. This calls `rl_redisplay()` in the underlying library.

6.7.3 History file

The following functions operate on a history file:

`readline.`**`read_history_file`**([*filename*])

Load a readline history file, and append it to the history list. The default filename is `~/.history`. This calls `read_history()` in the underlying library.

`readline.`**`write_history_file`**([*filename*])

Save the history list to a readline history file, overwriting any existing file. The default filename is `~/.history`. This calls `write_history()` in the underlying library.

readline.**append_history_file**(*nelements*[, *filename*])

Append the last *nelements* items of history to a file. The default filename is `~/.history`. The file must already exist. This calls `append_history()` in the underlying library. This function only exists if Python was compiled for a version of the library that supports it.

Added in version 3.5.

readline.**get_history_length**()

readline.**set_history_length**(*length*)

Set or return the desired number of lines to save in the history file. The *write_history_file()* function uses this value to truncate the history file, by calling `history_truncate_file()` in the underlying library. Negative values imply unlimited history file size.

6.7.4 History list

The following functions operate on a global history list:

readline.**clear_history**()

Clear the current history. This calls `clear_history()` in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports it.

readline.**get_current_history_length**()

Return the number of items currently in the history. (This is different from *get_history_length()*, which returns the maximum number of lines that will be written to a history file.)

readline.**get_history_item**(*index*)

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

readline.**remove_history_item**(*pos*)

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

readline.**replace_history_item**(*pos*, *line*)

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

readline.**add_history**(*line*)

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

readline.**set_auto_history**(*enabled*)

Enable or disable automatic calls to `add_history()` when reading input via readline. The *enabled* argument should be a Boolean value that when true, enables auto history, and that when false, disables auto history.

Added in version 3.6.

CPython implementation detail: Auto history is enabled by default, and changes to this do not persist across multiple sessions.

6.7.5 Startup hooks

readline.**set_startup_hook**([*function*])

Set or remove the function invoked by the `rl_startup_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before readline prints the first prompt.

readline.**set_pre_input_hook**([*function*])

Set or remove the function invoked by the `rl_pre_input_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before readline

starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

6.7.6 Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, Readline is set up to be used by *rlcompleter* to complete Python identifiers for the interactive interpreter. If the *readline* module is to be used with a custom completer, a different set of word delimiters should be set.

`readline.`**`set_completer`**`(`[*function*]`)`

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text, state)`, for *state* in `0`, `1`, `2`, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the *entry_func* callback passed to `rl_completion_matches()` in the underlying library. The *text* string comes from the first parameter to the `rl_attempted_completion_function` callback of the underlying library.

`readline.`**`get_completer`**`()`

Get the completer function, or `None` if no completer function has been set.

`readline.`**`get_completion_type`**`()`

Get the type of completion being attempted. This returns the `rl_completion_type` variable in the underlying library as an integer.

`readline.`**`get_begidx`**`()`

`readline.`**`get_endidx`**`()`

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the `rl_attempted_completion_function` callback of the underlying library. The values may be different in the same input editing scenario based on the underlying C readline implementation. Ex: libedit is known to behave differently than libreadline.

`readline.`**`set_completer_delims`**`(`*string*`)`

`readline.`**`get_completer_delims`**`()`

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the `rl_completer_word_break_characters` variable in the underlying library.

`readline.`**`set_completion_display_matches_hook`**`(`[*function*]`)`

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or `None`, any completion display function already installed is removed. This sets or clears the `rl_completion_display_matches_hook` callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

6.7.7 Example

The following example demonstrates how to use the *readline* module's history reading and writing functions to automatically load and save a history file named `.python_history` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```
import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")
try:
```

(continues on next page)

(continued from previous page)

```
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow unruly
    readline.set_history_length(1000)
except FileNotFoundError:
    pass

atexit.register(readline.write_history_file, histfile)
```

This code is actually automatically run when Python is run in interactive mode (see *Readline configuration*).

The following example achieves the same goal but supports concurrent interactive sessions, by only appending the new history.

```
import atexit
import os
import readline
histfile = os.path.join(os.path.expanduser("~"), ".python_history")

try:
    readline.read_history_file(histfile)
    h_len = readline.get_current_history_length()
except FileNotFoundError:
    open(histfile, 'wb').close()
    h_len = 0

def save(prev_h_len, histfile):
    new_h_len = readline.get_current_history_length()
    readline.set_history_length(1000)
    readline.append_history_file(new_h_len - prev_h_len, histfile)
atexit.register(save, h_len, histfile)
```

The following example extends the *code.InteractiveConsole* class to support history save/restore.

```
import atexit
import code
import os
import readline

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/.console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except FileNotFoundError:
                pass
            atexit.register(self.save_history, histfile)

    def save_history(self, histfile):
        readline.set_history_length(1000)
        readline.write_history_file(histfile)
```

6.8 rlcompleter — Completion function for GNU readline

Source code: Lib/rlcompleter.py

The rlcompleter module defines a completion function suitable to be passed to *set_completer()* in the *readline* module.

When this module is imported on a Unix platform with the *readline* module available, an instance of the *Completer* class is automatically created and its *complete()* method is set as the *readline completer*. The method provides completion of valid Python identifiers and keywords.

Example:

```
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer(  readline.read_init_file(
readline.__file__         readline.insert_text(      readline.set_completer(
readline.__name__         readline.parse_and_bind(
>>> readline.
```

The rlcompleter module is designed for use with Python's interactive mode. Unless Python is run with the -S option, the module is automatically imported and configured (see *Readline configuration*).

On platforms without *readline*, the *Completer* class defined by this module can still be used for custom purposes.

class rlcompleter.**Completer**

Completer objects have the following method:

complete(*text*, *state*)

Return the next possible completion for *text*.

When called by the *readline* module, this method is called successively with state == 0, 1, 2, ... until the method returns None.

If called for *text* that doesn't include a period character ('.'), it will complete from names currently defined in *__main__*, *builtins* and keywords (as defined by the *keyword* module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to __getattr__()) up to the last part, and find matches for the rest via the *dir()* function. Any exception raised during the evaluation of the expression is caught, silenced and *None* is returned.

CHAPTER

SEVEN

BINARY DATA SERVICES

The modules described in this chapter provide some basic services operations for manipulation of binary data. Other operations on binary data, specifically in relation to file formats and network protocols, are described in the relevant sections.

Some libraries described under *Text Processing Services* also work with either ASCII-compatible binary formats (for example, `re`) or all binary data (for example, `difflib`).

In addition, see the documentation for Python's built-in binary data types in *Binary Sequence Types — bytes, bytearray, memoryview*.

7.1 `struct` — Interpret bytes as packed binary data

Source code: Lib/struct.py

This module converts between Python values and C structs represented as Python `bytes` objects. Compact *format strings* describe the intended conversions to/from Python values. The module's functions and objects can be used for two largely distinct applications, data exchange with external sources (files or network connections), or data transfer between the Python application and the C layer.

> **Note**
>
> When no prefix character is given, native mode is the default. It packs or unpacks data based on the platform and compiler on which the Python interpreter was built. The result of packing a given C struct includes pad bytes which maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. In contrast, when communicating data between external sources, the programmer is responsible for defining byte ordering and padding between elements. See *Byte Order, Size, and Alignment* for details.

Several `struct` functions (and methods of `Struct`) take a *buffer* argument. This refers to objects that implement the bufferobjects and provide either a readable or read-writable buffer. The most common types used for that purpose are `bytes` and `bytearray`, but many other types that can be viewed as an array of bytes implement the buffer protocol, so that they can be read/filled without additional copying from a `bytes` object.

7.1.1 Functions and Exceptions

The module defines the following exception and functions:

exception `struct.`**error**

Exception raised on various occasions; argument is a string describing what is wrong.

`struct.`**pack**(*format*, *v1*, *v2*, ...)

Return a bytes object containing the values *v1*, *v2*, … packed according to the format string *format*. The arguments must match the values required by the format exactly.

struct.**pack_into**(*format*, *buffer*, *offset*, *v1*, *v2*, ...)

Pack the values *v1*, *v2*, … according to the format string *format* and write the packed bytes into the writable buffer *buffer* starting at position *offset*. Note that *offset* is a required argument.

struct.**unpack**(*format*, *buffer*)

Unpack from the buffer *buffer* (presumably packed by `pack(format, ...)`) according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes must match the size required by the format, as reflected by `calcsize()`.

struct.**unpack_from**(*format*, */*, *buffer*, *offset=0*)

Unpack from *buffer* starting at position *offset*, according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes, starting at position *offset*, must be at least the size required by the format, as reflected by `calcsize()`.

struct.**iter_unpack**(*format*, *buffer*)

Iteratively unpack from the buffer *buffer* according to the format string *format*. This function returns an iterator which will read equally sized chunks from the buffer until all its contents have been consumed. The buffer's size in bytes must be a multiple of the size required by the format, as reflected by `calcsize()`.

Each iteration yields a tuple as specified by the format string.

Added in version 3.4.

struct.**calcsize**(*format*)

Return the size of the struct (and hence of the bytes object produced by `pack(format, ...)`) corresponding to the format string *format*.

7.1.2 Format Strings

Format strings describe the data layout when packing and unpacking data. They are built up from *format characters*, which specify the type of data being packed/unpacked. In addition, special characters control the *byte order, size and alignment*. Each format string consists of an optional prefix character which describes the overall properties of the data and one or more format characters which describe the actual data values and padding.

Byte Order, Size, and Alignment

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler). This behavior is chosen so that the bytes of a packed struct correspond exactly to the memory layout of the corresponding C struct. Whether to use native byte ordering and padding or standard formats depends on the application.

Alternatively, the first character of the format string can be used to indicate the byte order, size and alignment of the packed data, according to the following table:

Character	Byte order	Size	Alignment
`@`	native	native	native
`=`	native	standard	none
`<`	little-endian	standard	none
`>`	big-endian	standard	none
`!`	network (= big-endian)	standard	none

If the first character is not one of these, `'@'` is assumed.

Note

The number 1023 (`0x3ff` in hexadecimal) has the following byte representations:

- `03 ff` in big-endian (`>`)

- `ff 03` in little-endian (<)

Python example:

```
>>> import struct
>>> struct.pack('>h', 1023)
b'\x03\xff'
>>> struct.pack('<h', 1023)
b'\xff\x03'
```

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86, AMD64 (x86-64), and Apple M1 are little-endian; IBM z and many legacy architectures are big-endian. Use *sys.byteorder* to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character; see the table in the *Format Characters* section.

Note the difference between `'@'` and `'='`: both use native byte order, but the size and alignment of the latter is standardized.

The form `'!'` represents the network byte order which is always big-endian as defined in IETF RFC 1700.

There is no way to indicate non-native byte order (force byte-swapping); use the appropriate choice of `'<'` or `'>'`.

Notes:

(1) Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.

(2) No padding is added when using non-native size and alignment, e.g. with '<', '>', '=', and '!'.

(3) To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See *Examples*.

Format Characters

Format characters have the following meaning; the conversion between C and Python values should be obvious given their types. The 'Standard size' column refers to the size of the packed value in bytes when using standard size; that is, when the format string starts with one of `'<'`, `'>'`, `'!'` or `'='`. When using native size, the size of the packed value is platform-dependent.

Format	C Type	Python type	Standard size	Notes
x	pad byte	no value		(7)
c	char	bytes of length 1	1	
b	signed char	integer	1	(1), (2)
B	unsigned char	integer	1	(2)
?	_Bool	bool	1	(1)
h	short	integer	2	(2)
H	unsigned short	integer	2	(2)
i	int	integer	4	(2)
I	unsigned int	integer	4	(2)
l	long	integer	4	(2)
L	unsigned long	integer	4	(2)
q	long long	integer	8	(2)
Q	unsigned long long	integer	8	(2)
n	ssize_t	integer		(3)
N	size_t	integer		(3)
e	(6)	float	2	(4)
f	float	float	4	(4)
d	double	float	8	(4)
s	char[]	bytes		(9)
p	char[]	bytes		(8)
P	void*	integer		(5)

Changed in version 3.3: Added support for the `'n'` and `'N'` formats.

Changed in version 3.6: Added support for the `'e'` format.

Notes:

(1) The `'?'` conversion code corresponds to the `_Bool` type defined by C standards since C99. In standard mode, it is represented by one byte.

(2) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a `__index__()` method then that method is called to convert the argument to an integer before packing.

Changed in version 3.2: Added use of the `__index__()` method for non-integers.

(3) The `'n'` and `'N'` conversion codes are only available for the native size (selected as the default or with the `'@'` byte order character). For the standard size, you can use whichever of the other integer formats fits your application.

(4) For the `'f'`, `'d'` and `'e'` conversion codes, the packed representation uses the IEEE 754 binary32, binary64 or binary16 format (for `'f'`, `'d'` or `'e'` respectively), regardless of the floating-point format used by the platform.

(5) The `'P'` format character is only available for the native byte ordering (selected as the default or with the `'@'` byte order character). The byte order character `'='` chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the `'P'` format is not available.

(6) The IEEE 754 binary16 "half precision" type was introduced in the 2008 revision of the IEEE 754 standard. It has a sign bit, a 5-bit exponent and 11-bit precision (with 10 bits explicitly stored), and can represent numbers between approximately `6.1e-05` and `6.5e+04` at full precision. This type is not widely supported by C compilers: on a typical machine, an unsigned short can be used for storage, but not for math operations. See the Wikipedia page on the half-precision floating-point format for more information.

(7) When packing, `'x'` inserts one NUL byte.

(8) The `'p'` format character encodes a "Pascal string", meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to *pack()* is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it

is padded with null bytes so that exactly count bytes in all are used. Note that for *unpack()*, the `'p'` format character consumes `count` bytes, but that the string returned can never contain more than 255 bytes.

(9) For the `'s'` format character, the count is interpreted as the length of the bytes, not a repeat count like for the other format characters; for example, `'10s'` means a single 10-byte string mapping to or from a single Python byte string, while `'10c'` means 10 separate one byte character elements (e.g., `cccccccccc`) mapping to or from ten different Python byte objects. (See *Examples* for a concrete demonstration of the difference.) If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting bytes object always has exactly the specified number of bytes. As a special case, `'0s'` means a single, empty string (while `'0c'` means 0 characters).

A format character may be preceded by an integral repeat count. For example, the format string `'4h'` means exactly the same as `'hhhh'`.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

When packing a value `x` using one of the integer formats (`'b'`, `'B'`, `'h'`, `'H'`, `'i'`, `'I'`, `'l'`, `'L'`, `'q'`, `'Q'`), if `x` is outside the valid range for that format then *struct.error* is raised.

Changed in version 3.1: Previously, some of the integer formats wrapped out-of-range values and raised *DeprecationWarning* instead of *struct.error*.

For the `'?'` format character, the return value is either *True* or *False*. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be `True` when unpacking.

Examples

Note

Native byte order examples (designated by the `'@'` format prefix or lack of any prefix character) may not match what the reader's machine produces as that depends on the platform and compiler.

Pack and unpack integers of three different sizes, using big endian ordering:

```
>>> from struct import *
>>> pack(">bhl", 1, 2, 3)
b'\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('>bhl', b'\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('>bhl')
7
```

Attempt to pack an integer which is too large for the defined field:

```
>>> pack(">h", 99999)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
struct.error: 'h' format requires -32768 <= number <= 32767
```

Demonstrate the difference between `'s'` and `'c'` format characters:

```
>>> pack("@ccc", b'1', b'2', b'3')
b'123'
>>> pack("@3s", b'123')
b'123'
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple:

```
>>> record = b'raymond   \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name=b'raymond   ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size in native mode since padding is implicit. In standard mode, the user is responsible for inserting any desired padding. Note in the first `pack` call below that three NUL bytes were added after the packed `'#'` to align the following integer on a four-byte boundary. In this example, the output was produced on a little endian machine:

```
>>> pack('@ci', b'#', 0x12131415)
b'#\x00\x00\x00\x15\x14\x13\x12'
>>> pack('@ic', 0x12131415, b'#')
b'\x15\x14\x13\x12#'
>>> calcsize('@ci')
8
>>> calcsize('@ic')
5
```

The following format `'llh0l'` results in two pad bytes being added at the end, assuming the platform's longs are aligned on 4-byte boundaries:

```
>>> pack('@llh0l', 1, 2, 3)
b'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

Module *pickle*
Python object serialization.

7.1.3 Applications

Two main applications for the *struct* module exist, data interchange between Python and C code within an application or another application compiled using the same compiler (*native formats*), and data interchange between applications using agreed upon data layout (*standard formats*). Generally speaking, the format strings constructed for these two domains are distinct.

Native Formats

When constructing format strings which mimic native layouts, the compiler and machine architecture determine byte ordering and padding. In such cases, the `@` format character should be used to specify native byte ordering and data sizes. Internal pad bytes are normally inserted automatically. It is possible that a zero-repeat format code will be needed at the end of a format string to round up to the correct byte boundary for proper alignment of consecutive chunks of data.

Consider these two simple examples (on a 64-bit, little-endian machine):

```
>>> calcsize('@lhl')
24
```

(continues on next page)

(continued from previous page)

```
>>> calcsize('@llh')
18
```

Data is not padded to an 8-byte boundary at the end of the second format string without the use of extra padding. A zero-repeat format code solves that problem:

```
>>> calcsize('@llh0l')
24
```

The `'x'` format code can be used to specify the repeat, but for native formats it is better to use a zero-repeat format like `'0l'`.

By default, native byte ordering and alignment is used, but it is better to be explicit and use the `'@'` prefix character.

Standard Formats

When exchanging data beyond your process such as networking or storage, be precise. Specify the exact byte order, size, and alignment. Do not assume they match the native order of a particular machine. For example, network byte order is big-endian, while many popular CPUs are little-endian. By defining this explicitly, the user need not care about the specifics of the platform their code is running on. The first character should typically be `<` or `>` (or `!`). Padding is the responsibility of the programmer. The zero-repeat format character won't work. Instead, the user must explicitly add `'x'` pad bytes where needed. Revisiting the examples from the previous section, we have:

```
>>> calcsize('<qh6xq')
24
>>> pack('<qh6xq', 1, 2, 3) == pack('@lhl', 1, 2, 3)
True
>>> calcsize('@llh')
18
>>> pack('@llh', 1, 2, 3) == pack('<qqh', 1, 2, 3)
True
>>> calcsize('<qqh6x')
24
>>> calcsize('@llh0l')
24
>>> pack('@llh0l', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
True
```

The above results (executed on a 64-bit machine) aren't guaranteed to match when executed on different machines. For example, the examples below were executed on a 32-bit machine:

```
>>> calcsize('<qqh6x')
24
>>> calcsize('@llh0l')
12
>>> pack('@llh0l', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
False
```

7.1.4 Classes

The *struct* module also defines the following type:

class struct.**Struct**(*format*)

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a `Struct` object once and calling its methods is more efficient than calling module-level functions with the same format since the format string is only compiled once.

> **Note**
>
> The compiled versions of the most recent format strings passed to the module-level functions are cached, so programs that use only a few format strings needn't worry about reusing a single `Struct` instance.

Compiled Struct objects support the following methods and attributes:

pack(*v1*, *v2*, ...)

Identical to the `pack()` function, using the compiled format. (`len(result)` will equal `size`.)

pack_into(*buffer*, *offset*, *v1*, *v2*, ...)

Identical to the `pack_into()` function, using the compiled format.

unpack(*buffer*)

Identical to the `unpack()` function, using the compiled format. The buffer's size in bytes must equal `size`.

unpack_from(*buffer*, *offset=0*)

Identical to the `unpack_from()` function, using the compiled format. The buffer's size in bytes, starting at position *offset*, must be at least `size`.

iter_unpack(*buffer*)

Identical to the `iter_unpack()` function, using the compiled format. The buffer's size in bytes must be a multiple of `size`.

Added in version 3.4.

format

The format string used to construct this Struct object.

Changed in version 3.7: The format string type is now `str` instead of `bytes`.

size

The calculated size of the struct (and hence of the bytes object produced by the `pack()` method) corresponding to `format`.

Changed in version 3.13: The *repr()* of structs has changed. It is now:

```
>>> Struct('i')
Struct('i')
```

7.2 codecs — Codec registry and base classes

Source code: Lib/codecs.py

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry, which manages the codec and error handling lookup process. Most standard codecs are *text encodings*, which encode text to bytes (and decode bytes to text), but there are also codecs provided that encode text to text, and bytes to bytes. Custom codecs may encode and decode between arbitrary types, but some module features are restricted to be used specifically with *text encodings* or with codecs that encode to `bytes`.

The module defines the following functions for encoding and decoding with any codec:

codecs.**encode**(*obj*, *encoding='utf-8'*, *errors='strict'*)

Encodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is `'strict'` meaning that encoding errors raise `ValueError` (or a more codec specific subclass, such as `UnicodeEncodeError`). Refer to *Codec Base Classes* for more information on codec error handling.

codecs.**decode**(*obj*, *encoding='utf-8'*, *errors='strict'*)

Decodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is `'strict'` meaning that decoding errors raise `ValueError` (or a more codec specific subclass, such as `UnicodeDecodeError`). Refer to *Codec Base Classes* for more information on codec error handling.

The full details for each codec can also be looked up directly:

codecs.**lookup**(*encoding*)

Looks up the codec info in the Python codec registry and returns a `CodecInfo` object as defined below.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no `CodecInfo` object is found, a `LookupError` is raised. Otherwise, the `CodecInfo` object is stored in the cache and returned to the caller.

class codecs.**CodecInfo**(*encode*, *decode*, *streamreader=None*, *streamwriter=None*, *incrementalencoder=None*, *incrementaldecoder=None*, *name=None*)

Codec details when looking up the codec registry. The constructor arguments are stored in attributes of the same name:

name

The name of the encoding.

encode

decode

The stateless encoding and decoding functions. These must be functions or methods which have the same interface as the `encode()` and `decode()` methods of Codec instances (see *Codec Interface*). The functions or methods are expected to work in a stateless mode.

incrementalencoder

incrementaldecoder

Incremental encoder and decoder classes or factory functions. These have to provide the interface defined by the base classes `IncrementalEncoder` and `IncrementalDecoder`, respectively. Incremental codecs can maintain state.

streamwriter

streamreader

Stream writer and reader classes or factory functions. These have to provide the interface defined by the base classes `StreamWriter` and `StreamReader`, respectively. Stream codecs can maintain state.

To simplify access to the various codec components, the module provides these additional functions which use `lookup()` for the codec lookup:

codecs.**getencoder**(*encoding*)

Look up the codec for the given encoding and return its encoder function.

Raises a `LookupError` in case the encoding cannot be found.

codecs.**getdecoder**(*encoding*)

Look up the codec for the given encoding and return its decoder function.

Raises a `LookupError` in case the encoding cannot be found.

codecs.**getincrementalencoder**(*encoding*)

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a `LookupError` in case the encoding cannot be found or the codec doesn't support an incremental encoder.

codecs.**getincrementaldecoder**(*encoding*)

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental decoder.

codecs.**getreader**(*encoding*)

Look up the codec for the given encoding and return its *StreamReader* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

codecs.**getwriter**(*encoding*)

Look up the codec for the given encoding and return its *StreamWriter* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

Custom codecs are made available by registering a suitable codec search function:

codecs.**register**(*search_function*)

Register a codec search function. Search functions are expected to take one argument, being the encoding name in all lower case letters with hyphens and spaces converted to underscores, and return a *CodecInfo* object. In case a search function cannot find a given encoding, it should return `None`.

Changed in version 3.9: Hyphens and spaces are converted to underscore.

codecs.**unregister**(*search_function*)

Unregister a codec search function and clear the registry's cache. If the search function is not registered, do nothing.

Added in version 3.10.

While the builtin *open()* and the associated *io* module are the recommended approach for working with encoded text files, this module provides additional utility functions and classes that allow the use of a wider range of codecs when working with binary files:

codecs.**open**(*filename*, *mode='r'*, *encoding=None*, *errors='strict'*, *buffering=-1*)

Open an encoded file using the given *mode* and return an instance of *StreamReaderWriter*, providing transparent encoding/decoding. The default file mode is `'r'`, meaning to open the file in read mode.

> **Note**
>
> If *encoding* is not `None`, then the underlying encoded files are always opened in binary mode. No automatic conversion of `'\n'` is done on reading and writing. The *mode* argument may be any binary mode acceptable to the built-in *open()* function; the `'b'` is automatically added.

encoding specifies the encoding which is to be used for the file. Any encoding that encodes to and decodes from bytes is allowed, and the data types supported by the file methods depend on the codec used.

errors may be given to define the error handling. It defaults to `'strict'` which causes a *ValueError* to be raised in case an encoding error occurs.

buffering has the same meaning as for the built-in *open()* function. It defaults to -1 which means that the default buffer size will be used.

Changed in version 3.11: The `'U'` mode has been removed.

codecs.**EncodedFile**(*file*, *data_encoding*, *file_encoding=None*, *errors='strict'*)

Return a *StreamRecoder* instance, a wrapped version of *file* which provides transparent transcoding. The original file is closed when the wrapped version is closed.

Data written to the wrapped file is decoded according to the given *data_encoding* and then written to the original file as bytes using *file_encoding*. Bytes read from the original file are decoded according to *file_encoding*, and the result is encoded using *data_encoding*.

If *file_encoding* is not given, it defaults to *data_encoding*.

errors may be given to define the error handling. It defaults to `'strict'`, which causes *ValueError* to be raised in case an encoding error occurs.

codecs.**iterencode**(*iterator*, *encoding*, *errors='strict'*, ***kwargs*)

Uses an incremental encoder to iteratively encode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental encoder.

This function requires that the codec accept text *str* objects to encode. Therefore it does not support bytes-to-bytes encoders such as `base64_codec`.

codecs.**iterdecode**(*iterator*, *encoding*, *errors='strict'*, ***kwargs*)

Uses an incremental decoder to iteratively decode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental decoder.

This function requires that the codec accept *bytes* objects to decode. Therefore it does not support text-to-text encoders such as `rot_13`, although `rot_13` may be used equivalently with *iterencode()*.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

codecs.**BOM**

codecs.**BOM_BE**

codecs.**BOM_LE**

codecs.**BOM_UTF8**

codecs.**BOM_UTF16**

codecs.**BOM_UTF16_BE**

codecs.**BOM_UTF16_LE**

codecs.**BOM_UTF32**

codecs.**BOM_UTF32_BE**

codecs.**BOM_UTF32_LE**

These constants define various byte sequences, being Unicode byte order marks (BOMs) for several encodings. They are used in UTF-16 and UTF-32 data streams to indicate the byte order used, and in UTF-8 as a Unicode signature. *BOM_UTF16* is either *BOM_UTF16_BE* or *BOM_UTF16_LE* depending on the platform's native byte order, *BOM* is an alias for *BOM_UTF16*, *BOM_LE* for *BOM_UTF16_LE* and *BOM_BE* for *BOM_UTF16_BE*. The others represent the BOM in UTF-8 and UTF-32 encodings.

7.2.1 Codec Base Classes

The *codecs* module defines a set of base classes which define the interfaces for working with codec objects, and can also be used as the basis for custom codec implementations.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols. Codec authors also need to define how the codec will handle encoding and decoding errors.

Error Handlers

To simplify and standardize error handling, codecs may implement different error handling schemes by accepting the *errors* string argument:

```
>>> 'German ß, ♬'.encode(encoding='ascii', errors='backslashreplace')
b'German \\xdf, \\u266c'
>>> 'German ß, ♬'.encode(encoding='ascii', errors='xmlcharrefreplace')
b'German &#223;, &#9836;'
```

The following error handlers can be used with all Python *Standard Encodings* codecs:

Value	Meaning
`'strict'`	Raise *UnicodeError* (or a subclass), this is the default. Implemented in *strict_errors()*.
`'ignore'`	Ignore the malformed data and continue without further notice. Implemented in *ignore_errors()*.
`'replace'`	Replace with a replacement marker. On encoding, use `?` (ASCII character). On decoding, use `&#xFFFD;` (U+FFFD, the official REPLACEMENT CHARACTER). Implemented in *replace_errors()*.
`'backslashreplace'`	Replace with backslashed escape sequences. On encoding, use hexadecimal form of Unicode code point with formats `\xhh` `\uxxxx` `\Uxxxxxxxx`. On decoding, use hexadecimal form of byte value with format `\xhh`. Implemented in *backslashreplace_errors()*.
`'surrogateescape'`	On decoding, replace byte with individual surrogate code ranging from `U+DC80` to `U+DCFF`. This code will then be turned back into the same byte when the `'surrogateescape'` error handler is used when encoding the data. (See **PEP 383** for more.)

The following error handlers are only applicable to encoding (within *text encodings*):

Value	Meaning
`'xmlcharrefreplace'`	Replace with XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;`. Implemented in *xmlcharrefreplace_errors()*.
`'namereplace'`	Replace with `\N{...}` escape sequences, what appears in the braces is the Name property from Unicode Character Database. Implemented in *namereplace_errors()*.

In addition, the following error handler is specific to the given codecs:

Value	Codecs	Meaning
`'surrogatepass'`	utf-8, utf-16, utf-32, utf-16-be, utf-16-le, utf-32-be, utf-32-le	Allow encoding and decoding surrogate code point (`U+D800` - `U+DFFF`) as normal code point. Otherwise these codecs treat the presence of surrogate code point in *str* as an error.

Added in version 3.1: The `'surrogateescape'` and `'surrogatepass'` error handlers.

Changed in version 3.4: The `'surrogatepass'` error handler now works with utf-16* and utf-32* codecs.

Added in version 3.5: The `'namereplace'` error handler.

Changed in version 3.5: The `'backslashreplace'` error handler now works with decoding and translating.

The set of allowed values can be extended by registering a new named error handler:

`codecs.`**`register_error`**(*name*, *error_handler*)

Register the error handling function *error_handler* under the name *name*. The *error_handler* argument will be called during encoding and decoding in case of an error, when *name* is specified as the errors parameter.

For encoding, *error_handler* will be called with a *UnicodeEncodeError* instance, which contains information about the location of the error. The error handler must either raise this or a different exception, or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The replacement may be either *str* or *bytes*. If the replacement is bytes, the encoder will simply copy them into the output buffer. If the replacement is a string, the encoder will encode the replacement. Encoding continues on original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an *IndexError* will be raised.

Decoding and translating works similarly, except *UnicodeDecodeError* or *UnicodeTranslateError* will be passed to the handler and that the replacement from the error handler will be put into the output directly.

Previously registered error handlers (including the standard error handlers) can be looked up by name:

codecs.**lookup_error**(*name*)

Return the error handler previously registered under the name *name*.

Raises a *LookupError* in case the handler cannot be found.

The following standard error handlers are also made available as module level functions:

codecs.**strict_errors**(*exception*)

Implements the `'strict'` error handling.

Each encoding or decoding error raises a *UnicodeError*.

codecs.**ignore_errors**(*exception*)

Implements the `'ignore'` error handling.

Malformed data is ignored; encoding or decoding is continued without further notice.

codecs.**replace_errors**(*exception*)

Implements the `'replace'` error handling.

Substitutes `?` (ASCII character) for encoding errors or `\ufffd` (U+FFFD, the official REPLACEMENT CHARACTER) for decoding errors.

codecs.**backslashreplace_errors**(*exception*)

Implements the `'backslashreplace'` error handling.

Malformed data is replaced by a backslashed escape sequence. On encoding, use the hexadecimal form of Unicode code point with formats `\xhh` `\uxxxx` `\Uxxxxxxxx`. On decoding, use the hexadecimal form of byte value with format `\xhh`.

Changed in version 3.5: Works with decoding and translating.

codecs.**xmlcharrefreplace_errors**(*exception*)

Implements the `'xmlcharrefreplace'` error handling (for encoding within *text encoding* only).

The unencodable character is replaced by an appropriate XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;` .

codecs.**namereplace_errors**(*exception*)

Implements the `'namereplace'` error handling (for encoding within *text encoding* only).

The unencodable character is replaced by a `\N{...}` escape sequence. The set of characters that appear in the braces is the Name property from Unicode Character Database. For example, the German lowercase letter `'ß'` will be converted to byte sequence `\N{LATIN SMALL LETTER SHARP S}`.

Added in version 3.5.

Stateless Encoding and Decoding

The base *Codec* class defines these methods which also define the function interfaces of the stateless encoder and decoder:

class codecs.**Codec**

encode(*input*, *errors='strict'*)

Encodes the object *input* and returns a tuple (output object, length consumed). For instance, *text encoding* converts a string object to a bytes object using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

The *errors* argument defines the error handling to apply. It defaults to `'strict'` handling.

The method may not store state in the *Codec* instance. Use *StreamWriter* for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

decode(*input*, *errors='strict'*)

Decodes the object *input* and returns a tuple (output object, length consumed). For instance, for a *text encoding*, decoding converts a bytes object encoded using a particular character set encoding to a string object.

For text encodings and bytes-to-bytes codecs, *input* must be a bytes object or one which provides the read-only buffer interface – for example, buffer objects and memory mapped files.

The *errors* argument defines the error handling to apply. It defaults to `'strict'` handling.

The method may not store state in the `Codec` instance. Use `StreamReader` for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

Incremental Encoding and Decoding

The `IncrementalEncoder` and `IncrementalDecoder` classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the `encode()`/`decode()` method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the `encode()`/`decode()` method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

IncrementalEncoder Objects

The `IncrementalEncoder` class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

class codecs.**IncrementalEncoder**(*errors='strict'*)

Constructor for an `IncrementalEncoder` instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The `IncrementalEncoder` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `IncrementalEncoder` object.

encode(*object*, *final=False*)

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to `encode()` *final* must be true (the default is false).

reset()

Reset the encoder to the initial state. The output is discarded: call `.encode(object, final=True)`, passing an empty byte or text string if necessary, to reset the encoder and to get the output.

getstate()

Return the current state of the encoder which must be an integer. The implementation should make sure that `0` is the most common state. (States that are more complicated than integers can be converted into an integer by marshaling/pickling the state and encoding the bytes of the resulting string into an integer.)

setstate(*state*)

Set the state of the encoder to *state*. *state* must be an encoder state returned by `getstate()`.

IncrementalDecoder Objects

The *IncrementalDecoder* class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

class codecs.**IncrementalDecoder**(*errors='strict'*)

Constructor for an *IncrementalDecoder* instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalDecoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalDecoder* object.

decode(*object*, *final=False*)

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to *decode()* *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

reset()

Reset the decoder to the initial state.

getstate()

Return the current state of the decoder. This must be a tuple with two items, the first must be the buffer containing the still undecoded input. The second must be an integer and can be additional state info. (The implementation should make sure that `0` is the most common additional state info.) If this additional state info is `0` it must be possible to set the decoder to the state which has no input buffered and `0` as the additional state info, so that feeding the previously buffered input to the decoder returns it to the previous state without producing any output. (Additional state info that is more complicated than integers can be converted into an integer by marshaling/pickling the info and encoding the bytes of the resulting string into an integer.)

setstate(*state*)

Set the state of the decoder to *state*. *state* must be a decoder state returned by *getstate()*.

Stream Encoding and Decoding

The *StreamWriter* and *StreamReader* classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

StreamWriter Objects

The *StreamWriter* class is a subclass of *Codec* and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

class codecs.**StreamWriter**(*stream*, *errors='strict'*)

Constructor for a *StreamWriter* instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for writing text or binary data, as appropriate for the specific codec.

The *StreamWriter* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamWriter` object.

write(*object*)

Writes the object's contents encoded to the stream.

writelines(*list*)

Writes the concatenated iterable of strings to the stream (possibly by reusing the `write()` method). Infinite or very large iterables are not supported. The standard bytes-to-bytes codecs do not support this method.

reset()

Resets the codec buffers used for keeping internal state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the `StreamWriter` must also inherit all other methods and attributes from the underlying stream.

StreamReader Objects

The `StreamReader` class is a subclass of `Codec` and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

class codecs.**StreamReader**(*stream*, *errors='strict'*)

Constructor for a `StreamReader` instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for reading text or binary data, as appropriate for the specific codec.

The `StreamReader` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamReader` object.

The set of allowed values for the *errors* argument can be extended with `register_error()`.

read(*size=-1*, *chars=-1*, *firstline=False*)

Decodes data from the stream and returns the resulting object.

The *chars* argument indicates the number of decoded code points or bytes to return. The `read()` method will never return more data than requested, but it might return less, if there is not enough available.

The *size* argument indicates the approximate maximum number of encoded bytes or code points to read for decoding. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. This parameter is intended to prevent having to decode huge files in one step.

The *firstline* flag indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

readline(*size=None*, *keepends=True*)

Read one line from the input stream and return the decoded data.

size, if given, is passed as size argument to the stream's `read()` method.

If *keepends* is false line-endings will be stripped from the lines returned.

readlines(*sizehint=None*, *keepends=True*)

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's `decode()` method and are included in the list entries if *keepends* is true.

sizehint, if given, is passed as the *size* argument to the stream's `read()` method.

reset()

Resets the codec buffers used for keeping internal state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the `StreamReader` must also inherit all other methods and attributes from the underlying stream.

StreamReaderWriter Objects

The `StreamReaderWriter` is a convenience class that allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the `lookup()` function to construct the instance.

class codecs.**StreamReaderWriter**(*stream*, *Reader*, *Writer*, *errors='strict'*)

Creates a `StreamReaderWriter` instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the `StreamReader` and `StreamWriter` interface resp. Error handling is done in the same way as defined for the stream readers and writers.

`StreamReaderWriter` instances define the combined interfaces of `StreamReader` and `StreamWriter` classes. They inherit all other methods and attributes from the underlying stream.

StreamRecoder Objects

The `StreamRecoder` translates data from one encoding to another, which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the `lookup()` function to construct the instance.

class codecs.**StreamRecoder**(*stream*, *encode*, *decode*, *Reader*, *Writer*, *errors='strict'*)

Creates a `StreamRecoder` instance which implements a two-way conversion: *encode* and *decode* work on the frontend — the data visible to code calling `read()` and `write()`, while *Reader* and *Writer* work on the backend — the data in *stream*.

You can use these objects to do transparent transcodings, e.g., from Latin-1 to UTF-8 and back.

The *stream* argument must be a file-like object.

The *encode* and *decode* arguments must adhere to the `Codec` interface. *Reader* and *Writer* must be factory functions or classes providing objects of the `StreamReader` and `StreamWriter` interface respectively.

Error handling is done in the same way as defined for the stream readers and writers.

`StreamRecoder` instances define the combined interfaces of `StreamReader` and `StreamWriter` classes. They inherit all other methods and attributes from the underlying stream.

7.2.2 Encodings and Unicode

Strings are stored internally as sequences of code points in range `U+0000–U+10FFFF`. (See **PEP 393** for more details about the implementation.) Once a string object is used outside of CPU and memory, endianness and how these arrays are stored as bytes become an issue. As with other codecs, serialising a string into a sequence of bytes is known as

encoding, and recreating the string from the sequence of bytes is known as *decoding*. There are a variety of different text serialisation codecs, which are collectivity referred to as *text encodings*.

The simplest text encoding (called `'latin-1'` or `'iso-8859-1'`) maps the code points 0–255 to the bytes `0x0–0xff`, which means that a string object that contains code points above `U+00FF` can't be encoded with this codec. Doing so will raise a *`UnicodeEncodeError`* that looks like the following (although the details of the error message may differ): `UnicodeEncodeError: 'latin-1' codec can't encode character '\u1234' in position 3: ordinal not in range(256).`

There's another group of encodings (the so called charmap encodings) that choose a different subset of all Unicode code points and how these code points are mapped to the bytes `0x0–0xff`. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in Unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called `UTF-32-BE` and `UTF-32-LE` respectively. Their disadvantage is that if e.g. you use `UTF-32-BE` on a little endian machine you will always have to swap bytes on encoding and decoding. `UTF-32` avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a `UTF-16` or `UTF-32` byte sequence, there's the so called BOM ("Byte Order Mark"). This is the Unicode character `U+FEFF`. This character can be prepended to every `UTF-16` or `UTF-32` byte sequence. The byte swapped version of this character (`0xFFFE`) is an illegal character that may not appear in a Unicode text. So when the first character in a `UTF-16` or `UTF-32` byte sequence appears to be a `U+FFFE` the bytes have to be swapped on decoding. Unfortunately the character `U+FEFF` had a second purpose as a `ZERO WIDTH NO-BREAK SPACE`: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using `U+FEFF` as a `ZERO WIDTH NO-BREAK SPACE` has been deprecated (with `U+2060` (`WORD JOINER`) assuming this role). Nevertheless Unicode software still must be able to handle `U+FEFF` in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a string; as a `ZERO WIDTH NO-BREAK SPACE` it's a normal character that will be decoded like any other.

There's another encoding that is able to encode the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four `1` bits followed by a `0` bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

Range	Encoding
`U-00000000` … `U-0000007F`	0xxxxxxx
`U-00000080` … `U-000007FF`	110xxxxx 10xxxxxx
`U-00000800` … `U-0000FFFF`	1110xxxx 10xxxxxx 10xxxxxx
`U-00010000` … `U-0010FFFF`	11110xxx 10xxxxxx 10xxxxxx 10xxxxxx

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any `U+FEFF` character in the decoded string (even if it's the first character) is treated as a `ZERO WIDTH NO-BREAK SPACE`.

Without external information it's impossible to reliably determine which encoding was used for encoding a string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python calls `"utf-8-sig"`) for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence: `0xef`, `0xbb`, `0xbf`) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

> LATIN SMALL LETTER I WITH DIAERESIS
> RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK
> INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a `utf-8-sig` encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the utf-8-sig codec will write `0xef`, `0xbb`, `0xbf` as the first three bytes to the file. On decoding `utf-8-sig` will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

7.2.3 Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. `'utf-8'` is a valid alias for the `'utf_8'` codec.

CPython implementation detail: Some common encodings can bypass the codecs lookup machinery to improve performance. These optimization opportunities are only recognized by CPython for a limited set of (case insensitive) aliases: utf-8, utf8, latin-1, latin1, iso-8859-1, iso8859-1, mbcs (Windows only), ascii, us-ascii, utf-16, utf16, utf-32, utf32, and the same using underscores instead of dashes. Using alternative aliases for these encodings may result in slower execution.

Changed in version 3.6: Optimization opportunity recognized for us-ascii.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

Codec	Aliases	Languages
ascii	646, us-ascii	English
big5	big5-tw, csbig5	Traditional Chinese
big5hkscs	big5-hkscs, hkscs	Traditional Chinese
cp037	IBM037, IBM039	English
cp273	273, IBM273, csIBM273	German Added in version 3.4.
cp424	EBCDIC-CP-HE, IBM424	Hebrew

utf_7	U7, unicode-1-1-utf-7	all languages
utf_8	U8, UTF, utf8, cp65001	all languages
utf_8_sig		all languages

Changed in version 3.4: The utf-16* and utf-32* encoders no longer allow surrogate code points (`U+D800–U+DFFF`) to be encoded. The utf-32* decoders no longer decode byte sequences that correspond to surrogate code points.

Changed in version 3.8: `cp65001` is now an alias to `utf_8`.

7.2.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated meaning describes the encoding direction.

Text Encodings

The following codecs provide `str` to `bytes` encoding and *bytes-like object* to `str` decoding, similar to the Unicode text encodings.

Codec	Aliases	Meaning
idna		Implement **RFC 3490**, see also `encodings.idna`. Only `errors='strict'` is supported.
mbcs	ansi, dbcs	Windows only: Encode the operand according to the ANSI codepage (CP_ACP).
oem		Windows only: Encode the operand according to the OEM codepage (CP_OEMCP). Added in version 3.6.
palmos		Encoding of PalmOS 3.5.
punycode		Implement **RFC 3492**. Stateful codecs are not supported.
raw_unicode_escape		Latin-1 encoding with `\u`*XXXX* and `\U`*XXXXXXXX* for other code points. Existing backslashes are not escaped in any way. It is used in the Python pickle protocol.
undefined		Raise an exception for all conversions, even empty strings. The error handler is ignored.
unicode_escape		Encoding suitable as the contents of a Unicode literal in ASCII-encoded Python source code, except that quotes are not escaped. Decode from Latin-1 source code. Beware that Python source code actually uses UTF-8 by default.

Changed in version 3.8: “unicode_internal” codec is removed.

Binary Transforms

The following codecs provide binary transforms: *bytes-like object* to `bytes` mappings. They are not supported by `bytes.decode()` (which only produces `str` output).

Codec	Aliases	Meaning	Encoder / decoder
base64_codec[1]	base64, base_64	Convert the operand to multiline MIME base64 (the result always includes a trailing `'\n'`). Changed in version 3.4: accepts any *bytes-like object* as input for encoding and decoding	*base64.encodebytes()* / *base64.decodebytes()*
bz2_codec	bz2	Compress the operand using bz2.	*bz2.compress()* / *bz2.decompress()*
hex_codec	hex	Convert the operand to hexadecimal representation, with two digits per byte.	*binascii.b2a_hex()* / *binascii.a2b_hex()*
quopri_codec	quopri, quotedprintable, quoted_printa	Convert the operand to MIME quoted printable.	*quopri.encode()* with `quotetabs=True` / *quopri.decode()*
uu_codec	uu	Convert the operand using uuencode.	
zlib_codec	zip, zlib	Compress the operand using gzip.	*zlib.compress()* / *zlib.decompress()*

Added in version 3.2: Restoration of the binary transforms.

Changed in version 3.4: Restoration of the aliases for the binary transforms.

Text Transforms

The following codec provides a text transform: a *str* to *str* mapping. It is not supported by *str.encode()* (which only produces *bytes* output).

Codec	Aliases	Meaning
rot_13	rot13	Return the Caesar-cypher encryption of the operand.

Added in version 3.2: Restoration of the `rot_13` text transform.

Changed in version 3.4: Restoration of the `rot13` alias.

7.2.5 `encodings.idna` — Internationalized Domain Names in Applications

This module implements **RFC 3490** (Internationalized Domain Names in Applications) and **RFC 3492** (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and *stringprep*.

If you need the IDNA 2008 standard from **RFC 5891** and **RFC 5895**, use the third-party idna module.

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

[1] In addition to *bytes-like objects*, `'base64_codec'` also accepts ASCII-only instances of *str* for decoding

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in **section 3.1 of RFC 3490** and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the *socket* module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the socket module. On top of that, modules that have host names as function parameters, such as *http.client* and *ftplib*, accept Unicode host names (*http.client* then also transparently sends an IDNA hostname in the *Host* field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: applications wishing to present such host names to the user should decode them to Unicode.

The module *encodings.idna* also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.`**`nameprep`**(*label*)

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is true.

`encodings.idna.`**`ToASCII`**(*label*)

Convert a label to ASCII, as specified in **RFC 3490**. `UseSTD3ASCIIRules` is assumed to be false.

`encodings.idna.`**`ToUnicode`**(*label*)

Convert a label to Unicode, as specified in **RFC 3490**.

7.2.6 `encodings.mbcs` — Windows ANSI codepage

This module implements the ANSI codepage (CP_ACP).

Availability: Windows.

Changed in version 3.2: Before 3.2, the *errors* argument was ignored; `'replace'` was always used to encode, and `'ignore'` to decode.

Changed in version 3.3: Support any error handler.

7.2.7 `encodings.utf_8_sig` — UTF-8 codec with BOM signature

This module implements a variant of the UTF-8 codec. On encoding, a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). On decoding, an optional UTF-8 encoded BOM at the start of the data will be skipped.

CHAPTER

EIGHT

DATA TYPES

The modules described in this chapter provide a variety of specialized data types such as dates and times, fixed-type arrays, heap queues, double-ended queues, and enumerations.

Python also provides some built-in data types, in particular, `dict`, `list`, `set` and `frozenset`, and `tuple`. The `str` class is used to hold Unicode strings, and the `bytes` and `bytearray` classes are used to hold binary data.

The following modules are documented in this chapter:

8.1 `datetime` — Basic date and time types

Source code: Lib/datetime.py

The `datetime` module supplies classes for manipulating dates and times.

While date and time arithmetic is supported, the focus of the implementation is on efficient attribute extraction for output formatting and manipulation.

Tip

Skip to *the format codes*.

See also

Module `calendar`
General calendar related functions.

Module `time`
Time access and conversions.

Module `zoneinfo`
Concrete time zones representing the IANA time zone database.

Package dateutil
Third-party library with expanded time zone and parsing support.

Package DateType
Third-party library that introduces distinct static types to e.g. allow *static type checkers* to differentiate between naive and aware datetimes.

8.1.1 Aware and Naive Objects

Date and time objects may be categorized as "aware" or "naive" depending on whether or not they include time zone information.

With sufficient knowledge of applicable algorithmic and political time adjustments, such as time zone and daylight saving time information, an **aware** object can locate itself relative to other aware objects. An aware object represents a specific moment in time that is not open to interpretation.[1]

A **naive** object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other time zone is purely up to the program, just like it is up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, *datetime* and *time* objects have an optional time zone information attribute, `tzinfo`, that can be set to an instance of a subclass of the abstract *tzinfo* class. These *tzinfo* objects capture information about the offset from UTC time, the time zone name, and whether daylight saving time is in effect.

Only one concrete *tzinfo* class, the *timezone* class, is supplied by the `datetime` module. The `timezone` class can represent simple time zones with fixed offsets from UTC, such as UTC itself or North American EST and EDT time zones. Supporting time zones at deeper levels of detail is up to the application. The rules for time adjustment across the world are more political than rational, change frequently, and there is no standard suitable for every application aside from UTC.

8.1.2 Constants

The `datetime` module exports the following constants:

`datetime.`**`MINYEAR`**

The smallest year number allowed in a *date* or *datetime* object. *MINYEAR* is 1.

`datetime.`**`MAXYEAR`**

The largest year number allowed in a *date* or *datetime* object. *MAXYEAR* is 9999.

`datetime.`**`UTC`**

Alias for the UTC time zone singleton *datetime.timezone.utc*.

Added in version 3.11.

8.1.3 Available Types

`class` `datetime.`**`date`**

An idealized naive date, assuming the current Gregorian calendar always was, and always will be, in effect. Attributes: *year*, *month*, and *day*.

`class` `datetime.`**`time`**

An idealized time, independent of any particular day, assuming that every day has exactly 24*60*60 seconds. (There is no notion of "leap seconds" here.) Attributes: *hour*, *minute*, *second*, *microsecond*, and *tzinfo*.

`class` `datetime.`**`datetime`**

A combination of a date and a time. Attributes: *year*, *month*, *day*, *hour*, *minute*, *second*, *microsecond*, and *tzinfo*.

`class` `datetime.`**`timedelta`**

A duration expressing the difference between two *datetime* or *date* instances to microsecond resolution.

`class` `datetime.`**`tzinfo`**

An abstract base class for time zone information objects. These are used by the *datetime* and *time* classes to provide a customizable notion of time adjustment (for example, to account for time zone and/or daylight saving time).

`class` `datetime.`**`timezone`**

A class that implements the *tzinfo* abstract base class as a fixed offset from the UTC.

Added in version 3.2.

[1] If, that is, we ignore the effects of Relativity

Objects of these types are immutable.

Subclass relationships:

```
object
    timedelta
    tzinfo
        timezone
    time
    date
        datetime
```

Common Properties

The *date*, *datetime*, *time*, and *timezone* types share these common features:

- Objects of these types are immutable.
- Objects of these types are *hashable*, meaning that they can be used as dictionary keys.
- Objects of these types support efficient pickling via the *pickle* module.

Determining if an Object is Aware or Naive

Objects of the *date* type are always naive.

An object of type *time* or *datetime* may be aware or naive.

A *datetime* object `d` is aware if both of the following hold:

1. `d.tzinfo` is not `None`
2. `d.tzinfo.utcoffset(d)` does not return `None`

Otherwise, `d` is naive.

A *time* object `t` is aware if both of the following hold:

1. `t.tzinfo` is not `None`
2. `t.tzinfo.utcoffset(None)` does not return `None`.

Otherwise, `t` is naive.

The distinction between aware and naive doesn't apply to *timedelta* objects.

8.1.4 `timedelta` Objects

A *timedelta* object represents a duration, the difference between two *datetime* or *date* instances.

class datetime.**timedelta**(*days=0*, *seconds=0*, *microseconds=0*, *milliseconds=0*, *minutes=0*, *hours=0*, *weeks=0*)

All arguments are optional and default to 0. Arguments may be integers or floats, and may be positive or negative.

Only *days*, *seconds* and *microseconds* are stored internally. Arguments are converted to those units:

- A millisecond is converted to 1000 microseconds.
- A minute is converted to 60 seconds.
- An hour is converted to 3600 seconds.
- A week is converted to 7 days.

and days, seconds and microseconds are then normalized so that the representation is unique, with

- `0 <= microseconds < 1000000`

- `0 <= seconds < 3600*24` (the number of seconds in one day)
- `-999999999 <= days <= 999999999`

The following example illustrates how any arguments besides *days*, *seconds* and *microseconds* are "merged" and normalized into those three resulting attributes:

```
>>> from datetime import timedelta
>>> delta = timedelta(
...     days=50,
...     seconds=27,
...     microseconds=10,
...     milliseconds=29000,
...     minutes=5,
...     hours=8,
...     weeks=2
... )
>>> # Only days, seconds, and microseconds remain
>>> delta
datetime.timedelta(days=64, seconds=29156, microseconds=10)
```

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond using round-half-to-even tiebreaker. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

If the normalized value of days lies outside the indicated range, *OverflowError* is raised.

Note that normalization of negative values may be surprising at first. For example:

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

Since the string representation of `timedelta` objects can be confusing, use the following recipe to produce a more readable format:

```
>>> def pretty_timedelta(td):
...     if td.days >= 0:
...         return str(td)
...     return f'-({-td!s})'
...
>>> d = timedelta(hours=-1)
>>> str(d)  # not human-friendly
'-1 day, 23:00:00'
>>> pretty_timedelta(d)
'-(1:00:00)'
```

Class attributes:

`timedelta.`**`min`**

The most negative *timedelta* object, `timedelta(-999999999)`.

`timedelta.`**`max`**

The most positive *timedelta* object, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.`**`resolution`**

The smallest possible difference between non-equal *timedelta* objects, `timedelta(microseconds=1)`.

Note that, because of normalization, `timedelta.max` is greater than `-timedelta.min`. `-timedelta.max` is not representable as a *timedelta* object.

Instance attributes (read-only):

`timedelta.`**days**

Between -999,999,999 and 999,999,999 inclusive.

`timedelta.`**seconds**

Between 0 and 86,399 inclusive.

Caution

It is a somewhat common bug for code to unintentionally use this attribute when it is actually intended to get a *total_seconds()* value instead:

```
>>> from datetime import timedelta
>>> duration = timedelta(seconds=11235813)
>>> duration.days, duration.seconds
(130, 3813)
>>> duration.total_seconds()
11235813.0
```

`timedelta.`**microseconds**

Between 0 and 999,999 inclusive.

Supported operations:

Operation	Result
`t1 = t2 + t3`	Sum of `t2` and `t3`. Afterwards `t1 - t2 == t3` and `t1 - t3 == t2` are true. (1)
`t1 = t2 - t3`	Difference of `t2` and `t3`. Afterwards `t1 == t2 - t3` and `t2 == t1 + t3` are true. (1)(6)
`t1 = t2 * i or t1 = i * t2`	Delta multiplied by an integer. Afterwards `t1 // i == t2` is true, provided `i != 0`.
	In general, `t1 * i == t1 * (i-1) + t1` is true. (1)
`t1 = t2 * f or t1 = f * t2`	Delta multiplied by a float. The result is rounded to the nearest multiple of timedelta.resolution using round-half-to-even.
`f = t2 / t3`	Division (3) of overall duration `t2` by interval unit `t3`. Returns a *float* object.
`t1 = t2 / f or t1 = t2 / i`	Delta divided by a float or an int. The result is rounded to the nearest multiple of timedelta.resolution using round-half-to-even.
`t1 = t2 // i` or `t1 = t2 // t3`	The floor is computed and the remainder (if any) is thrown away. In the second case, an integer is returned. (3)
`t1 = t2 % t3`	The remainder is computed as a *timedelta* object. (3)
`q, r = divmod(t1, t2)`	Computes the quotient and the remainder: `q = t1 // t2` (3) and `r = t1 % t2`. `q` is an integer and `r` is a *timedelta* object.
`+t1`	Returns a *timedelta* object with the same value. (2)
`-t1`	Equivalent to `timedelta(-t1.days, -t1.seconds, -t1.microseconds)`, and to `t1 * -1`. (1)(4)
`abs(t)`	Equivalent to `+t` when `t.days >= 0`, and to `-t` when `t.days < 0`. (2)
`str(t)`	Returns a string in the form `[D day[s], ][H]H:MM:SS[.UUUUUU]`, where D is negative for negative `t`. (5)
`repr(t)`	Returns a string representation of the *timedelta* object as a constructor call with canonical attribute values.

Notes:

(1) This is exact but may overflow.

(2) This is exact and cannot overflow.

(3) Division by zero raises *ZeroDivisionError*.

(4) `-timedelta.max` is not representable as a *timedelta* object.

(5) String representations of *timedelta* objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:

```
>>> timedelta(hours=-5)
datetime.timedelta(days=-1, seconds=68400)
>>> print(_)
-1 day, 19:00:00
```

(6) The expression `t2 - t3` will always be equal to the expression `t2 + (-t3)` except when t3 is equal to `timedelta.max`; in that case the former will produce a result while the latter will overflow.

In addition to the operations listed above, *timedelta* objects support certain additions and subtractions with *date* and *datetime* objects (see below).

Changed in version 3.2: Floor division and true division of a *timedelta* object by another *timedelta* object are now supported, as are remainder operations and the *divmod()* function. True division and multiplication of a *timedelta* object by a *float* object are now supported.

timedelta objects support equality and order comparisons.

In Boolean contexts, a *timedelta* object is considered to be true if and only if it isn't equal to `timedelta(0)`.

Instance methods:

`timedelta.`**`total_seconds`**`()`

Return the total number of seconds contained in the duration. Equivalent to `td / timedelta(seconds=1)`. For interval units other than seconds, use the division form directly (e.g. `td / timedelta(microseconds=1)`).

Note that for very large time intervals (greater than 270 years on most platforms) this method will lose microsecond accuracy.

Added in version 3.2.

Examples of usage: `timedelta`

An additional example of normalization:

```
>>> # Components of another_year add up to exactly 365 days
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                          minutes=50, seconds=600)
>>> year == another_year
True
>>> year.total_seconds()
31536000.0
```

Examples of *timedelta* arithmetic:

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> ten_years = 10 * year
>>> ten_years
datetime.timedelta(days=3650)
>>> ten_years.days // 365
10
```

(continues on next page)

(continued from previous page)

```
>>> nine_years = ten_years - year
>>> nine_years
datetime.timedelta(days=3285)
>>> three_years = nine_years // 3
>>> three_years, three_years.days // 365
(datetime.timedelta(days=1095), 3)
```

8.1.5 `date` Objects

A *date* object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions.

January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on.[2]

class datetime.**date**(*year*, *month*, *day*)

All arguments are required. Arguments must be integers, in the following ranges:

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`

If an argument outside those ranges is given, *ValueError* is raised.

Other constructors, all class methods:

classmethod date.**today**()

Return the current local date.

This is equivalent to `date.fromtimestamp(time.time())`.

classmethod date.**fromtimestamp**(*timestamp*)

Return the local date corresponding to the POSIX timestamp, such as is returned by *time.time()*.

This may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `localtime()` function, and *OSError* on `localtime()` failure. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by *fromtimestamp()*.

Changed in version 3.3: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `localtime()` function. Raise *OSError* instead of *ValueError* on `localtime()` failure.

classmethod date.**fromordinal**(*ordinal*)

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1.

ValueError is raised unless `1 <= ordinal <= date.max.toordinal()`. For any date `d`, `date.fromordinal(d.toordinal()) == d`.

classmethod date.**fromisoformat**(*date_string*)

Return a *date* corresponding to a *date_string* given in any valid ISO 8601 format, with the following exceptions:

1. Reduced precision dates are not currently supported (`YYYY-MM`, `YYYY`).
2. Extended date representations are not currently supported (`±YYYYYY-MM-DD`).
3. Ordinal dates are not currently supported (`YYYY-OOO`).

Examples:

[2] This matches the definition of the "proleptic Gregorian" calendar in Dershowitz and Reingold's book *Calendrical Calculations*, where it's the base calendar for all computations. See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

```
>>> from datetime import date
>>> date.fromisoformat('2019-12-04')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('20191204')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('2021-W01-1')
datetime.date(2021, 1, 4)
```

Added in version 3.7.

Changed in version 3.11: Previously, this method only supported the format `YYYY-MM-DD`.

classmethod `date.`**fromisocalendar**(*year*, *week*, *day*)

Return a *date* corresponding to the ISO calendar date specified by year, week and day. This is the inverse of the function *date.isocalendar()*.

Added in version 3.8.

Class attributes:

`date.`**min**

The earliest representable date, `date(MINYEAR, 1, 1)`.

`date.`**max**

The latest representable date, `date(MAXYEAR, 12, 31)`.

`date.`**resolution**

The smallest possible difference between non-equal date objects, `timedelta(days=1)`.

Instance attributes (read-only):

`date.`**year**

Between *MINYEAR* and *MAXYEAR* inclusive.

`date.`**month**

Between 1 and 12 inclusive.

`date.`**day**

Between 1 and the number of days in the given month of the given year.

Supported operations:

Operation	Result
`date2 = date1 + timedelta`	`date2` will be `timedelta.days` days after `date1`. (1)
`date2 = date1 - timedelta`	Computes `date2` such that `date2 + timedelta == date1`. (2)
`timedelta = date1 - date2`	(3)
`date1 == date2` `date1 != date2`	Equality comparison. (4)

`date1 < date2`
`date1 > date2`
`date1 <= date2`
`date1 >= date2`
	Order comparison. (5)

Notes:

(1) *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days`. `timedelta.seconds` and `timedelta.microseconds` are ignored. *OverflowError* is raised if `date2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*.

(2) `timedelta.seconds` and `timedelta.microseconds` are ignored.

(3) This is exact, and cannot overflow. `timedelta.seconds` and `timedelta.microseconds` are 0, and `date2 + timedelta == date1` after.

(4) *date* objects are equal if they represent the same date.

`date` objects that are not also *datetime* instances are never equal to `datetime` objects, even if they represent the same date.

(5) *date1* is considered less than *date2* when *date1* precedes *date2* in time. In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`.

Order comparison between a `date` object that is not also a *datetime* instance and a `datetime` object raises *TypeError*.

Changed in version 3.13: Comparison between *datetime* object and an instance of the *date* subclass that is not a `datetime` subclass no longer converts the latter to `date`, ignoring the time part and the time zone. The default behavior can be changed by overriding the special comparison methods in subclasses.

In Boolean contexts, all *date* objects are considered to be true.

Instance methods:

`date.`**`replace`**(*year=self.year*, *month=self.month*, *day=self.day*)

Return a new *date* object with the same values, but with specified parameters updated.

Example:

```
>>> from datetime import date
>>> d = date(2002, 12, 31)
>>> d.replace(day=26)
datetime.date(2002, 12, 26)
```

The generic function *copy.replace()* also supports *date* objects.

`date.`**`timetuple`**()

Return a *time.struct_time* such as returned by *time.localtime()*.

The hours, minutes and seconds are 0, and the DST flag is -1.

`d.timetuple()` is equivalent to:

```
time.struct_time((d.year, d.month, d.day, 0, 0, 0, d.weekday(), yday, -1))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

`date.`**`toordinal`**()

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any *date* object `d`, `date.fromordinal(d.toordinal()) == d`.

`date.`**`weekday`**()

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. For example, `date(2002, 12, 4).weekday() == 2`, a Wednesday. See also *isoweekday()*.

`date.`**`isoweekday`**()

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. For example, `date(2002, 12, 4).isoweekday() == 3`, a Wednesday. See also *weekday()*, *isocalendar()*.

date.**isocalendar**()

Return a *named tuple* object with three components: `year`, `week` and `weekday`.

The ISO calendar is a widely used variant of the Gregorian calendar.[3]

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004:

```
>>> from datetime import date
>>> date(2003, 12, 29).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=1)
>>> date(2004, 1, 4).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=7)
```

Changed in version 3.9: Result changed from a tuple to a *named tuple*.

date.**isoformat**()

Return a string representing the date in ISO 8601 format, `YYYY-MM-DD`:

```
>>> from datetime import date
>>> date(2002, 12, 4).isoformat()
'2002-12-04'
```

date.**__str__**()

For a date `d`, `str(d)` is equivalent to `d.isoformat()`.

date.**ctime**()

Return a string representing the date:

```
>>> from datetime import date
>>> date(2002, 12, 4).ctime()
'Wed Dec  4 00:00:00 2002'
```

`d.ctime()` is equivalent to:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which *`time.ctime()`* invokes, but which *`date.ctime()`* does not invoke) conforms to the C standard.

date.**strftime**(*format*)

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. See also *strftime() and strptime() Behavior* and *`date.isoformat()`*.

date.**__format__**(*format*)

Same as *`date.strftime()`*. This makes it possible to specify a format string for a *`date`* object in formatted string literals and when using *`str.format()`*. See also *strftime() and strptime() Behavior* and *`date.isoformat()`*.

Examples of Usage: `date`

Example of counting days to an event:

[3] See R. H. van Gent's guide to the mathematics of the ISO 8601 calendar for a good explanation.

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
...
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

More examples of working with *date*:

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)

>>> # Methods related to formatting string output
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> d.ctime()
'Mon Mar 11 00:00:00 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'

>>> # Methods for to extracting 'components' under different calendars
>>> t = d.timetuple()
>>> for i in t:
...     print(i)
2002                # year
3                   # month
11                  # day
0
0
0
0                   # weekday (0 = Monday)
70                  # 70th day in the year
-1
>>> ic = d.isocalendar()
>>> for i in ic:
...     print(i)
2002                # ISO year
11                  # ISO week number
1                   # ISO day number ( 1 = Monday )

>>> # A date object is immutable; all operations produce a new object
```

(continues on next page)

(continued from previous page)

```
>>> d.replace(year=2005)
datetime.date(2005, 3, 11)
```

8.1.6 `datetime` Objects

A *datetime* object is a single object containing all the information from a *date* object and a *time* object.

Like a *date* object, *datetime* assumes the current Gregorian calendar extended in both directions; like a *time* object, *datetime* assumes there are exactly 3600*24 seconds in every day.

Constructor:

class datetime.**datetime**(*year*, *month*, *day*, *hour=0*, *minute=0*, *second=0*, *microsecond=0*, *tzinfo=None*, *, *fold=0*)

The *year*, *month* and *day* arguments are required. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments must be integers in the following ranges:

- `MINYEAR <= year <= MAXYEAR`,
- `1 <= month <= 12`,
- `1 <= day <= number of days in the given month and year`,
- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold in [0, 1]`.

If an argument outside those ranges is given, *ValueError* is raised.

Changed in version 3.6: Added the *fold* parameter.

Other constructors, all class methods:

classmethod datetime.**today**()

Return the current local date and time, with *tzinfo* `None`.

Equivalent to:

```
datetime.fromtimestamp(time.time())
```

See also *now()*, *fromtimestamp()*.

This method is functionally equivalent to *now()*, but without a `tz` parameter.

classmethod datetime.**now**(*tz=None*)

Return the current local date and time.

If optional argument *tz* is `None` or not specified, this is like *today()*, but, if possible, supplies more precision than can be gotten from going through a *time.time()* timestamp (for example, this may be possible on platforms supplying the C `gettimeofday()` function).

If *tz* is not `None`, it must be an instance of a *tzinfo* subclass, and the current date and time are converted to *tz*'s time zone.

This function is preferred over *today()* and *utcnow()*.

> **Note**
>
> Subsequent calls to `datetime.now()` may return the same instant depending on the precision of the underlying clock.

classmethod `datetime.`**utcnow**`()`

Return the current UTC date and time, with *tzinfo* `None`.

This is like *now()*, but returns the current UTC date and time, as a naive *datetime* object. An aware current UTC datetime can be obtained by calling `datetime.now(timezone.utc)`. See also *now()*.

> **Warning**
>
> Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing the current time in UTC is by calling `datetime.now(timezone.utc)`.

Deprecated since version 3.12: Use *datetime.now()* with *UTC* instead.

classmethod `datetime.`**fromtimestamp**`(`*timestamp*, *tz=None*`)`

Return the local date and time corresponding to the POSIX timestamp, such as is returned by *time.time()*. If optional argument *tz* is `None` or not specified, the timestamp is converted to the platform's local date and time, and the returned *datetime* object is naive.

If *tz* is not `None`, it must be an instance of a *tzinfo* subclass, and the timestamp is converted to *tz*'s time zone.

fromtimestamp() may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions, and *OSError* on `localtime()` or `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by *fromtimestamp()*, and then it's possible to have two timestamps differing by a second that yield identical *datetime* objects. This method is preferred over *utcfromtimestamp()*.

Changed in version 3.3: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. Raise *OSError* instead of *ValueError* on `localtime()` or `gmtime()` failure.

Changed in version 3.6: *fromtimestamp()* may return instances with *fold* set to 1.

classmethod `datetime.`**utcfromtimestamp**`(`*timestamp*`)`

Return the UTC *datetime* corresponding to the POSIX timestamp, with *tzinfo* `None`. (The resulting object is naive.)

This may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `gmtime()` function, and *OSError* on `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038.

To get an aware *datetime* object, call *fromtimestamp()*:

```
datetime.fromtimestamp(timestamp, timezone.utc)
```

On the POSIX compliant platforms, it is equivalent to the following expression:

```
datetime(1970, 1, 1, tzinfo=timezone.utc) + timedelta(seconds=timestamp)
```

except the latter formula always supports the full years range: between *MINYEAR* and *MAXYEAR* inclusive.

> **Warning**
>
> Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing a specific timestamp in UTC is by calling `datetime.fromtimestamp(timestamp, tz=timezone.utc)`.

Changed in version 3.3: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `gmtime()` function. Raise *OSError* instead of *ValueError* on `gmtime()` failure.

Deprecated since version 3.12: Use *datetime.fromtimestamp()* with *UTC* instead.

classmethod datetime.**fromordinal**(*ordinal*)

Return the *datetime* corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. *ValueError* is raised unless `1 <= ordinal <= datetime.max.toordinal()`. The hour, minute, second and microsecond of the result are all 0, and *tzinfo* is `None`.

classmethod datetime.**combine**(*date*, *time*, *tzinfo=time.tzinfo*)

Return a new *datetime* object whose date components are equal to the given *date* object's, and whose time components are equal to the given *time* object's. If the *tzinfo* argument is provided, its value is used to set the *tzinfo* attribute of the result, otherwise the *tzinfo* attribute of the *time* argument is used. If the *date* argument is a *datetime* object, its time components and *tzinfo* attributes are ignored.

For any *datetime* object `d`, `d == datetime.combine(d.date(), d.time(), d.tzinfo)`.

Changed in version 3.6: Added the *tzinfo* argument.

classmethod datetime.**fromisoformat**(*date_string*)

Return a *datetime* corresponding to a *date_string* in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The `T` separator may be replaced by any single unicode character.
3. Fractional hours and minutes are not supported.
4. Reduced precision dates are not currently supported (`YYYY-MM`, `YYYY`).
5. Extended date representations are not currently supported (`±YYYYYY-MM-DD`).
6. Ordinal dates are not currently supported (`YYYY-OOO`).

Examples:

```
>>> from datetime import datetime
>>> datetime.fromisoformat('2011-11-04')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('20111104')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('2011-11-04T00:05:23')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-11-04T00:05:23Z')
datetime.datetime(2011, 11, 4, 0, 5, 23, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('20111104T000523')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-W01-2T00:05:23.283')
datetime.datetime(2011, 1, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283+00:00')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000, tzinfo=datetime.timezone.utc)
```

(continues on next page)

(continued from previous page)

```
>>> datetime.fromisoformat('2011-11-04T00:05:23+04:00')
datetime.datetime(2011, 11, 4, 0, 5, 23,
    tzinfo=datetime.timezone(datetime.timedelta(seconds=14400)))
```

Added in version 3.7.

Changed in version 3.11: Previously, this method only supported formats that could be emitted by *date.isoformat()* or *datetime.isoformat()*.

classmethod datetime.**fromisocalendar**(*year*, *week*, *day*)

Return a *datetime* corresponding to the ISO calendar date specified by year, week and day. The non-date components of the datetime are populated with their normal default values. This is the inverse of the function *datetime.isocalendar()*.

Added in version 3.8.

classmethod datetime.**strptime**(*date_string*, *format*)

Return a *datetime* corresponding to *date_string*, parsed according to *format*.

If *format* does not contain microseconds or time zone information, this is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

ValueError is raised if the date_string and format can't be parsed by *time.strptime()* or if it returns a value which isn't a time tuple. See also *strftime() and strptime() Behavior* and *datetime.fromisoformat()*.

Changed in version 3.13: If *format* specifies a day of month without a year a *DeprecationWarning* is now emitted. This is to avoid a quadrennial leap year bug in code seeking to parse only a month and day as the default year used in absence of one in the format is not a leap year. Such *format* values may raise an error as of Python 3.15. The workaround is to always include a year in your *format*. If parsing *date_string* values that do not have a year, explicitly add a year that is a leap year before parsing:

```
>>> from datetime import datetime
>>> date_string = "02/29"
>>> when = datetime.strptime(f"{date_string};1984", "%m/%d;%Y")  # Avoids leap␣
↪year bug.
>>> when.strftime("%B %d")
'February 29'
```

Class attributes:

datetime.**min**

The earliest representable *datetime*, `datetime(MINYEAR, 1, 1, tzinfo=None)`.

datetime.**max**

The latest representable *datetime*, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

datetime.**resolution**

The smallest possible difference between non-equal *datetime* objects, `timedelta(microseconds=1)`.

Instance attributes (read-only):

datetime.**year**

Between *MINYEAR* and *MAXYEAR* inclusive.

datetime.**month**

Between 1 and 12 inclusive.

datetime.**day**

Between 1 and the number of days in the given month of the given year.

`datetime.`**`hour`**

In `range(24)`.

`datetime.`**`minute`**

In `range(60)`.

`datetime.`**`second`**

In `range(60)`.

`datetime.`**`microsecond`**

In `range(1000000)`.

`datetime.`**`tzinfo`**

The object passed as the *tzinfo* argument to the *datetime* constructor, or `None` if none was passed.

`datetime.`**`fold`**

In `[0, 1]`. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The values 0 and 1 represent, respectively, the earlier and later of the two moments with the same wall time representation.

Added in version 3.6.

Supported operations:

Operation	Result
`datetime2 = datetime1 + timedelta`	(1)
`datetime2 = datetime1 - timedelta`	(2)
`timedelta = datetime1 - datetime2`	(3)
`datetime1 == datetime2` `datetime1 != datetime2`	Equality comparison. (4)

`datetime1 < datetime2`
`datetime1 > datetime2`
`datetime1 <= datetime2`
`datetime1 >= datetime2`
	Order comparison. (5)

(1) `datetime2` is a duration of `timedelta` removed from `datetime1`, moving forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. The result has the same *tzinfo* attribute as the input datetime, and `datetime2 - datetime1 == timedelta` after. *OverflowError* is raised if `datetime2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*. Note that no time zone adjustments are done even if the input is an aware object.

(2) Computes the `datetime2` such that `datetime2 + timedelta == datetime1`. As for addition, the result has the same *tzinfo* attribute as the input datetime, and no time zone adjustments are done even if the input is aware.

(3) Subtraction of a *datetime* from a *datetime* is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, *TypeError* is raised.

If both are naive, or both are aware and have the same *tzinfo* attribute, the *tzinfo* attributes are ignored, and the result is a *timedelta* object `t` such that `datetime2 + t == datetime1`. No time zone adjustments are done in this case.

If both are aware and have different *tzinfo* attributes, `a-b` acts as if `a` and `b` were first converted to naive UTC datetimes. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

(4) *datetime* objects are equal if they represent the same date and time, taking into account the time zone.

Naive and aware `datetime` objects are never equal.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and *fold* attributes are ignored and the base datetimes are compared. If both comparands are aware and have different *tzinfo* attributes, the comparison acts as comparands were first converted to UTC datetimes except that the implementation never overflows. `datetime` instances in a repeated interval are never equal to `datetime` instances in other time zone.

(5) *datetime1* is considered less than *datetime2* when *datetime1* precedes *datetime2* in time, taking into account the time zone.

Order comparison between naive and aware *datetime* objects raises *TypeError*.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and *fold* attributes are ignored and the base datetimes are compared. If both comparands are aware and have different *tzinfo* attributes, the comparison acts as comparands were first converted to UTC datetimes except that the implementation never overflows.

Changed in version 3.3: Equality comparisons between aware and naive *datetime* instances don't raise *TypeError*.

Changed in version 3.13: Comparison between *datetime* object and an instance of the *date* subclass that is not a `datetime` subclass no longer converts the latter to `date`, ignoring the time part and the time zone. The default behavior can be changed by overriding the special comparison methods in subclasses.

Instance methods:

`datetime.`**`date`**`()`

Return *date* object with same year, month and day.

`datetime.`**`time`**`()`

Return *time* object with same hour, minute, second, microsecond and fold. *tzinfo* is `None`. See also method *timetz()*.

Changed in version 3.6: The fold value is copied to the returned *time* object.

`datetime.`**`timetz`**`()`

Return *time* object with same hour, minute, second, microsecond, fold, and tzinfo attributes. See also method *time()*.

Changed in version 3.6: The fold value is copied to the returned *time* object.

`datetime.`**`replace`**`(`*year=self.year*, *month=self.month*, *day=self.day*, *hour=self.hour*, *minute=self.minute*, *second=self.second*, *microsecond=self.microsecond*, *tzinfo=self.tzinfo*, ***, *fold=0*`)`

Return a new *datetime* object with the same attributes, but with specified parameters updated. Note that `tzinfo=None` can be specified to create a naive datetime from an aware datetime with no conversion of date and time data.

datetime objects are also supported by generic function *copy.replace()*.

Changed in version 3.6: Added the *fold* parameter.

`datetime.`**`astimezone`**`(`*tz=None*`)`

Return a *datetime* object with new *tzinfo* attribute *tz*, adjusting the date and time data so the result is the same UTC time as *self*, but in *tz*'s local time.

If provided, *tz* must be an instance of a *tzinfo* subclass, and its *utcoffset()* and *dst()* methods must not return `None`. If *self* is naive, it is presumed to represent time in the system time zone.

If called without arguments (or with `tz=None`) the system local time zone is assumed for the target time zone. The `.tzinfo` attribute of the converted datetime instance will be set to an instance of *timezone* with the zone name and offset obtained from the OS.

If `self.tzinfo` is *tz*, `self.astimezone(tz)` is equal to *self*: no adjustment of date or time data is performed. Else the result is local time in the time zone *tz*, representing the same UTC time as *self*: after `astz`

= dt.astimezone(tz), astz - astz.utcoffset() will have the same date and time data as dt - dt.utcoffset().

If you merely want to attach a *timezone* object *tz* to a datetime *dt* without adjustment of date and time data, use dt.replace(tzinfo=tz). If you merely want to remove the timezone object from an aware datetime *dt* without conversion of date and time data, use dt.replace(tzinfo=None).

Note that the default *tzinfo.fromutc()* method can be overridden in a *tzinfo* subclass to affect the result returned by *astimezone()*. Ignoring error cases, *astimezone()* acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new timezone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

Changed in version 3.3: *tz* now can be omitted.

Changed in version 3.6: The *astimezone()* method can now be called on naive instances that are presumed to represent system local time.

datetime.**utcoffset**()

If *tzinfo* is None, returns None, else returns self.tzinfo.utcoffset(self), and raises an exception if the latter doesn't return None or a *timedelta* object with magnitude less than one day.

Changed in version 3.7: The UTC offset is not restricted to a whole number of minutes.

datetime.**dst**()

If *tzinfo* is None, returns None, else returns self.tzinfo.dst(self), and raises an exception if the latter doesn't return None or a *timedelta* object with magnitude less than one day.

Changed in version 3.7: The DST offset is not restricted to a whole number of minutes.

datetime.**tzname**()

If *tzinfo* is None, returns None, else returns self.tzinfo.tzname(self), raises an exception if the latter doesn't return None or a string object,

datetime.**timetuple**()

Return a *time.struct_time* such as returned by *time.localtime()*.

d.timetuple() is equivalent to:

```
time.struct_time((d.year, d.month, d.day,
                  d.hour, d.minute, d.second,
                  d.weekday(), yday, dst))
```

where yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1 is the day number within the current year starting with 1 for January 1st. The *tm_isdst* flag of the result is set according to the *dst()* method: *tzinfo* is None or *dst()* returns None, tm_isdst is set to -1; else if *dst()* returns a non-zero value, tm_isdst is set to 1; else tm_isdst is set to 0.

datetime.**utctimetuple**()

If *datetime* instance d is naive, this is the same as d.timetuple() except that *tm_isdst* is forced to 0 regardless of what d.dst() returns. DST is never in effect for a UTC time.

If d is aware, d is normalized to UTC time, by subtracting d.utcoffset(), and a *time.struct_time* for the normalized time is returned. tm_isdst is forced to 0. Note that an *OverflowError* may be raised if d.year was MINYEAR or MAXYEAR and UTC adjustment spills over a year boundary.

> **Warning**
>
> Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC; as a result, using *`datetime.utctimetuple()`* may give misleading results. If you have a naive `datetime` representing UTC, use `datetime.replace(tzinfo=timezone.utc)` to make it aware, at which point you can use *`datetime.timetuple()`*.

`datetime.`**`toordinal`**`()`

Return the proleptic Gregorian ordinal of the date. The same as `self.date().toordinal()`.

`datetime.`**`timestamp`**`()`

Return POSIX timestamp corresponding to the *`datetime`* instance. The return value is a *`float`* similar to that returned by *`time.time()`*.

Naive *`datetime`* instances are assumed to represent local time and this method relies on the platform C `mktime()` function to perform the conversion. Since *`datetime`* supports wider range of values than `mktime()` on many platforms, this method may raise *`OverflowError`* or *`OSError`* for times far in the past or far in the future.

For aware *`datetime`* instances, the return value is computed as:

```
(dt - datetime(1970, 1, 1, tzinfo=timezone.utc)).total_seconds()
```

Added in version 3.3.

Changed in version 3.6: The *`timestamp()`* method uses the *`fold`* attribute to disambiguate the times during a repeated interval.

> **Note**
>
> There is no method to obtain the POSIX timestamp directly from a naive *`datetime`* instance representing UTC time. If your application uses this convention and your system time zone is not set to UTC, you can obtain the POSIX timestamp by supplying `tzinfo=timezone.utc`:
>
> ```
> timestamp = dt.replace(tzinfo=timezone.utc).timestamp()
> ```
>
> or by calculating the timestamp directly:
>
> ```
> timestamp = (dt - datetime(1970, 1, 1)) / timedelta(seconds=1)
> ```

`datetime.`**`weekday`**`()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also *`isoweekday()`*.

`datetime.`**`isoweekday`**`()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. The same as `self.date().isoweekday()`. See also *`weekday()`*, *`isocalendar()`*.

`datetime.`**`isocalendar`**`()`

Return a *named tuple* with three components: `year`, `week` and `weekday`. The same as `self.date().isocalendar()`.

`datetime.`**`isoformat`**`(`*sep='T'*, *timespec='auto'*`)`

Return a string representing the date and time in ISO 8601 format:

- `YYYY-MM-DDTHH:MM:SS.ffffff`, if *`microsecond`* is not 0
- `YYYY-MM-DDTHH:MM:SS`, if *`microsecond`* is 0

If *`utcoffset()`* does not return `None`, a string is appended, giving the UTC offset:

- `YYYY-MM-DDTHH:MM:SS.ffffff+HH:MM[:SS[.ffffff]]`, if *microsecond* is not 0
- `YYYY-MM-DDTHH:MM:SS+HH:MM[:SS[.ffffff]]`, if *microsecond* is 0

Examples:

```
>>> from datetime import datetime, timezone
>>> datetime(2019, 5, 18, 15, 17, 8, 132263).isoformat()
'2019-05-18T15:17:08.132263'
>>> datetime(2019, 5, 18, 15, 17, tzinfo=timezone.utc).isoformat()
'2019-05-18T15:17:00+00:00'
```

The optional argument *sep* (default `'T'`) is a one-character separator, placed between the date and time portions of the result. For example:

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     """A time zone with an arbitrary, constant -06:39 offset."""
...     def utcoffset(self, dt):
...         return timedelta(hours=-6, minutes=-39)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
'2002-12-25 00:00:00-06:39'
>>> datetime(2009, 11, 27, microsecond=100, tzinfo=TZ()).isoformat()
'2009-11-27T00:00:00.000100-06:39'
```

The optional argument *timespec* specifies the number of additional components of the time to include (the default is `'auto'`). It can be one of the following:

- `'auto'`: Same as `'seconds'` if *microsecond* is 0, same as `'microseconds'` otherwise.
- `'hours'`: Include the *hour* in the two-digit `HH` format.
- `'minutes'`: Include *hour* and *minute* in `HH:MM` format.
- `'seconds'`: Include *hour*, *minute*, and *second* in `HH:MM:SS` format.
- `'milliseconds'`: Include full time, but truncate fractional second part to milliseconds. `HH:MM:SS.sss` format.
- `'microseconds'`: Include full time in `HH:MM:SS.ffffff` format.

> **Note**
>
> Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument:

```
>>> from datetime import datetime
>>> datetime.now().isoformat(timespec='minutes')
'2002-12-25T00:00'
>>> dt = datetime(2015, 1, 1, 12, 30, 59, 0)
>>> dt.isoformat(timespec='microseconds')
'2015-01-01T12:30:59.000000'
```

Changed in version 3.6: Added the *timespec* parameter.

`datetime.__str__()`

For a *datetime* instance `d`, `str(d)` is equivalent to `d.isoformat(' ')`.

`datetime.ctime()`

Return a string representing the date and time:

```
>>> from datetime import datetime
>>> datetime(2002, 12, 4, 20, 30, 40).ctime()
'Wed Dec  4 20:30:40 2002'
```

The output string will *not* include time zone information, regardless of whether the input is aware or naive.

`d.ctime()` is equivalent to:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which *time.ctime()* invokes, but which *datetime.ctime()* does not invoke) conforms to the C standard.

`datetime.`**`strftime`**(*format*)

Return a string representing the date and time, controlled by an explicit format string. See also *strftime() and strptime() Behavior* and *datetime.isoformat()*.

`datetime.`**`__format__`**(*format*)

Same as *datetime.strftime()*. This makes it possible to specify a format string for a *datetime* object in formatted string literals and when using *str.format()*. See also *strftime() and strptime() Behavior* and *datetime.isoformat()*.

Examples of Usage: `datetime`

Examples of working with *datetime* objects:

```
>>> from datetime import datetime, date, time, timezone

>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)

>>> # Using datetime.now()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043)   # GMT +1
>>> datetime.now(timezone.utc)
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060, tzinfo=datetime.timezone.utc)

>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)

>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print(it)
...
2006    # year
11      # month
21      # day
16      # hour
30      # minute
0       # second
1       # weekday (0 = Monday)
325     # number of days since 1st January
```

(continues on next page)

(continued from previous page)

```
-1      # dst - method tzinfo.dst() returned None

>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print(it)
...
2006    # ISO year
47      # ISO week
2       # ISO weekday

>>> # Formatting a datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day
↪", "month", "time")
'The day is 21, the month is November, the time is 04:30PM.'
```

The example below defines a *tzinfo* subclass capturing time zone information for Kabul, Afghanistan, which used +4 UTC until 1945 and then +4:30 UTC thereafter:

```
from datetime import timedelta, datetime, tzinfo, timezone

class KabulTz(tzinfo):
    # Kabul used +4 until 1945, when they moved to +4:30
    UTC_MOVE_DATE = datetime(1944, 12, 31, 20, tzinfo=timezone.utc)

    def utcoffset(self, dt):
        if dt.year < 1945:
            return timedelta(hours=4)
        elif (1945, 1, 1, 0, 0) <= dt.timetuple()[:5] < (1945, 1, 1, 0, 30):
            # An ambiguous ("imaginary") half-hour range representing
            # a 'fold' in time due to the shift from +4 to +4:30.
            # If dt falls in the imaginary range, use fold to decide how
            # to resolve. See PEP495.
            return timedelta(hours=4, minutes=(30 if dt.fold else 0))
        else:
            return timedelta(hours=4, minutes=30)

    def fromutc(self, dt):
        # Follow same validations as in datetime.tzinfo
        if not isinstance(dt, datetime):
            raise TypeError("fromutc() requires a datetime argument")
        if dt.tzinfo is not self:
            raise ValueError("dt.tzinfo is not self")

        # A custom implementation is required for fromutc as
        # the input to this function is a datetime with utc values
        # but with a tzinfo set to self.
        # See datetime.astimezone or fromtimestamp.
        if dt.replace(tzinfo=timezone.utc) >= self.UTC_MOVE_DATE:
            return dt + timedelta(hours=4, minutes=30)
        else:
            return dt + timedelta(hours=4)

    def dst(self, dt):
```

(continues on next page)

(continued from previous page)

```
        # Kabul does not observe daylight saving time.
        return timedelta(0)

    def tzname(self, dt):
        if dt >= self.UTC_MOVE_DATE:
            return "+04:30"
        return "+04"
```

Usage of `KabulTz` from above:

```
>>> tz1 = KabulTz()

>>> # Datetime before the change
>>> dt1 = datetime(1900, 11, 21, 16, 30, tzinfo=tz1)
>>> print(dt1.utcoffset())
4:00:00

>>> # Datetime after the change
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=tz1)
>>> print(dt2.utcoffset())
4:30:00

>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(timezone.utc)
>>> dt3
datetime.datetime(2006, 6, 14, 8, 30, tzinfo=datetime.timezone.utc)
>>> dt2
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=KabulTz())
>>> dt2 == dt3
True
```

8.1.7 `time` Objects

A *time* object represents a (local) time of day, independent of any particular day, and subject to adjustment via a *tzinfo* object.

class `datetime.`**time**(*hour=0*, *minute=0*, *second=0*, *microsecond=0*, *tzinfo=None*, *, *fold=0*)

All arguments are optional. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments must be integers in the following ranges:

- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold in [0, 1]`.

If an argument outside those ranges is given, *ValueError* is raised. All default to 0 except *tzinfo*, which defaults to `None`.

Class attributes:

`time.`**min**

The earliest representable *time*, `time(0, 0, 0, 0)`.

`time.`**max**

The latest representable *time*, `time(23, 59, 59, 999999)`.

time.**resolution**

The smallest possible difference between non-equal *time* objects, `timedelta(microseconds=1)`, although note that arithmetic on *time* objects is not supported.

Instance attributes (read-only):

time.**hour**

In `range(24)`.

time.**minute**

In `range(60)`.

time.**second**

In `range(60)`.

time.**microsecond**

In `range(1000000)`.

time.**tzinfo**

The object passed as the tzinfo argument to the *time* constructor, or `None` if none was passed.

time.**fold**

In `[0, 1]`. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The values 0 and 1 represent, respectively, the earlier and later of the two moments with the same wall time representation.

Added in version 3.6.

time objects support equality and order comparisons, where `a` is considered less than `b` when `a` precedes `b` in time.

Naive and aware `time` objects are never equal. Order comparison between naive and aware `time` objects raises *TypeError*.

If both comparands are aware, and have the same *tzinfo* attribute, the `tzinfo` and `fold` attributes are ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

Changed in version 3.3: Equality comparisons between aware and naive *time* instances don't raise *TypeError*.

In Boolean contexts, a *time* object is always considered to be true.

Changed in version 3.5: Before Python 3.5, a *time* object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See bpo-13936 for full details.

Other constructor:

classmethod time.**fromisoformat**(*time_string*)

Return a *time* corresponding to a *time_string* in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The leading `T`, normally required in cases where there may be ambiguity between a date and a time, is not required.
3. Fractional seconds may have any number of digits (anything beyond 6 will be truncated).
4. Fractional hours and minutes are not supported.

Examples:

```
>>> from datetime import time
>>> time.fromisoformat('04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T04:23:01')
```

(continues on next page)

(continued from previous page)

```
datetime.time(4, 23, 1)
>>> time.fromisoformat('T042301')
datetime.time(4, 23, 1)
>>> time.fromisoformat('04:23:01.000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01,000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01+04:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone(datetime.
↪timedelta(seconds=14400)))
>>> time.fromisoformat('04:23:01Z')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.utc)
>>> time.fromisoformat('04:23:01+00:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.utc)
```

Added in version 3.7.

Changed in version 3.11: Previously, this method only supported formats that could be emitted by *time.isoformat()*.

Instance methods:

time.**replace**(*hour=self.hour*, *minute=self.minute*, *second=self.second*, *microsecond=self.microsecond*, *tzinfo=self.tzinfo*, ***, *fold=0*)

Return a new *time* with the same values, but with specified parameters updated. Note that `tzinfo=None` can be specified to create a naive *time* from an aware *time*, without conversion of the time data.

time objects are also supported by generic function *copy.replace()*.

Changed in version 3.6: Added the *fold* parameter.

time.**isoformat**(*timespec='auto'*)

Return a string representing the time in ISO 8601 format, one of:

- `HH:MM:SS.ffffff`, if *microsecond* is not 0
- `HH:MM:SS`, if *microsecond* is 0
- `HH:MM:SS.ffffff+HH:MM[:SS[.ffffff]]`, if *utcoffset()* does not return `None`
- `HH:MM:SS+HH:MM[:SS[.ffffff]]`, if *microsecond* is 0 and *utcoffset()* does not return `None`

The optional argument *timespec* specifies the number of additional components of the time to include (the default is `'auto'`). It can be one of the following:

- `'auto'`: Same as `'seconds'` if *microsecond* is 0, same as `'microseconds'` otherwise.
- `'hours'`: Include the *hour* in the two-digit `HH` format.
- `'minutes'`: Include *hour* and *minute* in `HH:MM` format.
- `'seconds'`: Include *hour*, *minute*, and *second* in `HH:MM:SS` format.
- `'milliseconds'`: Include full time, but truncate fractional second part to milliseconds. `HH:MM:SS.sss` format.
- `'microseconds'`: Include full time in `HH:MM:SS.ffffff` format.

> **Note**
>
> Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument.

Example:

```
>>> from datetime import time
>>> time(hour=12, minute=34, second=56, microsecond=123456).isoformat(timespec=
↪'minutes')
'12:34'
>>> dt = time(hour=12, minute=34, second=56, microsecond=0)
>>> dt.isoformat(timespec='microseconds')
'12:34:56.000000'
>>> dt.isoformat(timespec='auto')
'12:34:56'
```

Changed in version 3.6: Added the *timespec* parameter.

`time.__str__()`

For a time `t`, `str(t)` is equivalent to `t.isoformat()`.

`time.strftime(format)`

Return a string representing the time, controlled by an explicit format string. See also *strftime() and strptime() Behavior* and `time.isoformat()`.

`time.__format__(format)`

Same as `time.strftime()`. This makes it possible to specify a format string for a `time` object in formatted string literals and when using `str.format()`. See also *strftime() and strptime() Behavior* and `time.isoformat()`.

`time.utcoffset()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

Changed in version 3.7: The UTC offset is not restricted to a whole number of minutes.

`time.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return `None`, or a `timedelta` object with magnitude less than one day.

Changed in version 3.7: The DST offset is not restricted to a whole number of minutes.

`time.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return `None` or a string object.

Examples of Usage: `time`

Examples of working with a `time` object:

```
>>> from datetime import time, tzinfo, timedelta
>>> class TZ1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self,dt):
...         return "+01:00"
...     def  __repr__(self):
...         return f"{self.__class__.__name__}()"
...
>>> t = time(12, 10, 30, tzinfo=TZ1())
>>> t
datetime.time(12, 10, 30, tzinfo=TZ1())
>>> t.isoformat()
```

(continues on next page)

(continued from previous page)

```
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'+01:00'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 +01:00'
>>> 'The {} is {:%H:%M}.'.format("time", t)
'The time is 12:10.'
```

8.1.8 `tzinfo` Objects

class datetime.**tzinfo**

This is an abstract base class, meaning that this class should not be instantiated directly. Define a subclass of *tzinfo* to capture information about a particular time zone.

An instance of (a concrete subclass of) *tzinfo* can be passed to the constructors for *datetime* and *time* objects. The latter objects view their attributes as being in local time, and the *tzinfo* object supports methods revealing offset of local time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

You need to derive a concrete subclass, and (at least) supply implementations of the standard *tzinfo* methods needed by the *datetime* methods you use. The `datetime` module provides *timezone*, a simple concrete subclass of *tzinfo* which can represent time zones with fixed offset from UTC such as UTC itself or North American EST and EDT.

Special requirement for pickling: A *tzinfo* subclass must have an `__init__()` method that can be called with no arguments, otherwise it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of *tzinfo* may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware `datetime` objects. If in doubt, simply implement all of them.

tzinfo.**utcoffset**(*dt*)

Return offset of local time from UTC, as a *timedelta* object that is positive east of UTC. If local time is west of UTC, this should be negative.

This represents the *total* offset from UTC; for example, if a *tzinfo* object represents both time zone and DST adjustments, *utcoffset()* should return their sum. If the UTC offset isn't known, return `None`. Else the value returned must be a *timedelta* object strictly between `-timedelta(hours=24)` and `timedelta(hours=24)` (the magnitude of the offset must be less than one day). Most implementations of *utcoffset()* will probably look like one of these two:

```
return CONSTANT                 # fixed-offset class
return CONSTANT + self.dst(dt)  # daylight-aware class
```

If *utcoffset()* does not return `None`, *dst()* should not return `None` either.

The default implementation of *utcoffset()* raises *NotImplementedError*.

Changed in version 3.7: The UTC offset is not restricted to a whole number of minutes.

tzinfo.**dst**(*dt*)

Return the daylight saving time (DST) adjustment, as a *timedelta* object or `None` if DST information isn't known.

Return `timedelta(0)` if DST is not in effect. If DST is in effect, return the offset as a *timedelta* object (see *utcoffset()* for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by *utcoffset()*, so there's no need to consult *dst()* unless you're interested in obtaining DST info separately. For example, *datetime.timetuple()* calls its *tzinfo* attribute's *dst()* method to determine

how the *tm_isdst* flag should be set, and *tzinfo.fromutc()* calls *dst()* to account for DST changes when crossing time zones.

An instance *tz* of a *tzinfo* subclass that models both standard and daylight times must be consistent in this sense:

`tz.utcoffset(dt) - tz.dst(dt)`

must return the same result for every *datetime* *dt* with `dt.tzinfo == tz`. For sane *tzinfo* subclasses, this expression yields the time zone's "standard offset", which should not depend on the date or the time, but only on geographic location. The implementation of *datetime.astimezone()* relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a *tzinfo* subclass cannot guarantee this, it may be able to override the default implementation of *tzinfo.fromutc()* to work correctly with *astimezone()* regardless.

Most implementations of *dst()* will probably look like one of these two:

```
def dst(self, dt):
    # a fixed-offset class:  doesn't account for DST
    return timedelta(0)
```

or:

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time.

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

The default implementation of *dst()* raises *NotImplementedError*.

Changed in version 3.7: The DST offset is not restricted to a whole number of minutes.

`tzinfo.`**`tzname`**`(`*dt*`)`

Return the time zone name corresponding to the *datetime* object *dt*, as a string. Nothing about string names is defined by the `datetime` module, and there's no requirement that it mean anything in particular. For example, `"GMT"`, `"UTC"`, `"-500"`, `"-5:00"`, `"EDT"`, `"US/Eastern"`, `"America/New York"` are all valid replies. Return `None` if a string name isn't known. Note that this is a method rather than a fixed string primarily because some *tzinfo* subclasses will wish to return different names depending on the specific value of *dt* passed, especially if the *tzinfo* class is accounting for daylight time.

The default implementation of *tzname()* raises *NotImplementedError*.

These methods are called by a *datetime* or *time* object, in response to their methods of the same names. A *datetime* object passes itself as the argument, and a *time* object passes `None` as the argument. A *tzinfo* subclass's methods should therefore be prepared to accept a *dt* argument of `None`, or of class *datetime*.

When `None` is passed, it's up to the class designer to decide the best response. For example, returning `None` is appropriate if the class wishes to say that time objects don't participate in the *tzinfo* protocols. It may be more useful for `utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a *datetime* object is passed in response to a *datetime* method, `dt.tzinfo` is the same object as *self*. *tzinfo* methods can rely on this, unless user code calls *tzinfo* methods directly. The intent is that the *tzinfo* methods interpret *dt* as being in local time, and not need worry about objects in other time zones.

There is one more *tzinfo* method that a subclass may wish to override:

tzinfo.**fromutc**(*dt*)

This is called from the default *datetime.astimezone()* implementation. When called from that, `dt.tzinfo` is *self*, and *dt*'s date and time data are to be viewed as expressing a UTC time. The purpose of *fromutc()* is to adjust the date and time data, returning an equivalent datetime in *self*'s local time.

Most *tzinfo* subclasses should be able to inherit the default *fromutc()* implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default *fromutc()* implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations of *astimezone()* and *fromutc()* may not produce the result you want if the result is one of the hours straddling the moment the standard offset changes.

Skipping code for error cases, the default *fromutc()* implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst  # this is self's standard offset
    if delta:
        dt += delta   # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

In the following `tzinfo_examples.py` file there are some examples of *tzinfo* classes:

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)
SECOND = timedelta(seconds=1)

# A class capturing the platform's idea of local time.
# (May result in wrong values on historical times in
#  timezones where UTC offset and/or the DST rules had
#  changed in the past.)
import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
    DSTOFFSET = STDOFFSET

DSTDIFF = DSTOFFSET - STDOFFSET

class LocalTimezone(tzinfo):

    def fromutc(self, dt):
        assert dt.tzinfo is self
        stamp = (dt - datetime(1970, 1, 1, tzinfo=self)) // SECOND
        args = _time.localtime(stamp)[:6]
        dst_diff = DSTDIFF // SECOND
```

(continues on next page)

(continued from previous page)

```
        # Detect fold
        fold = (args == _time.localtime(stamp - dst_diff))
        return datetime(*args, microsecond=dt.microsecond,
                        tzinfo=self, fold=fold)

    def utcoffset(self, dt):
        if self._isdst(dt):
            return DSTOFFSET
        else:
            return STDOFFSET

    def dst(self, dt):
        if self._isdst(dt):
            return DSTDIFF
        else:
            return ZERO

    def tzname(self, dt):
        return _time.tzname[self._isdst(dt)]

    def _isdst(self, dt):
        tt = (dt.year, dt.month, dt.day,
              dt.hour, dt.minute, dt.second,
              dt.weekday(), 0, 0)
        stamp = _time.mktime(tt)
        tt = _time.localtime(stamp)
        return tt.tm_isdst > 0

        if start <= std_time < end - HOUR:
            # Daylight saving time
            return dst_time

Eastern  = USTimeZone(-5, "Eastern",  "EST", "EDT")
Central  = USTimeZone(-6, "Central",  "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific  = USTimeZone(-8, "Pacific",  "PST", "PDT")
```

Note that there are unavoidable subtleties twice per year in a *tzinfo* subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

```
  UTC   3:MM  4:MM  5:MM  6:MM  7:MM  8:MM
  EST  22:MM 23:MM  0:MM  1:MM  2:MM  3:MM
  EDT  23:MM  0:MM  1:MM  2:MM  3:MM  4:MM

start  22:MM 23:MM  0:MM  1:MM  3:MM  4:MM

  end  23:MM  0:MM  1:MM  1:MM  2:MM  3:MM
```

When DST starts (the "start" line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn't really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. For example, at the Spring forward transition of 2016, we get:

```
>>> from datetime import datetime, timezone
>>> from tzinfo_examples import HOUR, Eastern
>>> u0 = datetime(2016, 3, 13, 5, tzinfo=timezone.utc)
```

(continues on next page)

(continued from previous page)

```
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname())
...
05:00:00 UTC = 00:00:00 EST
06:00:00 UTC = 01:00:00 EST
07:00:00 UTC = 03:00:00 EDT
08:00:00 UTC = 04:00:00 EDT
```

When DST ends (the "end" line), there's a potentially worse problem: there's an hour that can't be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that's times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. *astimezone()* mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern, but earlier times have the *fold* attribute set to 0 and the later times have it set to 1. For example, at the Fall back transition of 2016, we get:

```
>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname(), t.fold)
...
04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0
```

Note that the *datetime* instances that differ only by the value of the *fold* attribute are considered equal in comparisons.

Applications that can't bear wall-time ambiguities should explicitly check the value of the *fold* attribute or avoid using hybrid *tzinfo* subclasses; there are no ambiguities when using *timezone*, or any other fixed-offset *tzinfo* subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

See also

zoneinfo
: The `datetime` module has a basic *timezone* class (for handling arbitrary fixed offsets from UTC) and its *timezone.utc* attribute (a UTC `timezone` instance).

  `zoneinfo` brings the *IANA time zone database* (also known as the Olson database) to Python, and its usage is recommended.

IANA time zone database
: The Time Zone Database (often called tz, tzdata or zoneinfo) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

8.1.9 `timezone` Objects

The *timezone* class is a subclass of *tzinfo*, each instance of which represents a time zone defined by a fixed offset from UTC.

Objects of this class cannot be used to represent time zone information in the locations where different offsets are used in different days of the year or where historical changes have been made to civil time.

class datetime.**timezone**(*offset*, *name=None*)

The *offset* argument must be specified as a *timedelta* object representing the difference between the local time and UTC. It must be strictly between `-timedelta(hours=24)` and `timedelta(hours=24)`, otherwise *ValueError* is raised.

The *name* argument is optional. If specified it must be a string that will be used as the value returned by the *datetime.tzname()* method.

Added in version 3.2.

Changed in version 3.7: The UTC offset is not restricted to a whole number of minutes.

timezone.**utcoffset**(*dt*)

Return the fixed value specified when the *timezone* instance is constructed.

The *dt* argument is ignored. The return value is a *timedelta* instance equal to the difference between the local time and UTC.

Changed in version 3.7: The UTC offset is not restricted to a whole number of minutes.

timezone.**tzname**(*dt*)

Return the fixed value specified when the *timezone* instance is constructed.

If *name* is not provided in the constructor, the name returned by `tzname(dt)` is generated from the value of the `offset` as follows. If *offset* is `timedelta(0)`, the name is "UTC", otherwise it is a string in the format `UTC±HH:MM`, where ± is the sign of `offset`, HH and MM are two digits of `offset.hours` and `offset.minutes` respectively.

Changed in version 3.6: Name generated from `offset=timedelta(0)` is now plain `'UTC'`, not `'UTC+00:00'`.

timezone.**dst**(*dt*)

Always returns `None`.

timezone.**fromutc**(*dt*)

Return `dt + offset`. The *dt* argument must be an aware *datetime* instance, with `tzinfo` set to `self`.

Class attributes:

timezone.**utc**

The UTC time zone, `timezone(timedelta(0))`.

8.1.10 `strftime()` and `strptime()` Behavior

date, *datetime*, and *time* objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string.

Conversely, the *datetime.strptime()* class method creates a *datetime* object from a string representing a date and time and a corresponding format string.

The table below provides a high-level comparison of *strftime()* versus *strptime()*:

	strftime	strptime
Usage	Convert object to a string according to a given format	Parse a string into a *datetime* object given a corresponding format
Type of method	Instance method	Class method
Method of	*date*; *datetime*; *time*	*datetime*
Signature	`strftime(format)`	`strptime(date_string, format)`

`strftime()` and `strptime()` Format Codes

These methods accept format codes that can be used to parse and format dates:

```
>>> datetime.strptime('31/01/22 23:59:59.999999',
...                   '%d/%m/%y %H:%M:%S.%f')
datetime.datetime(2022, 1, 31, 23, 59, 59, 999999)
>>> _.strftime('%a %d %b %Y, %I:%M%p')
'Mon 31 Jan 2022, 11:59PM'
```

The following is a list of all the format codes that the 1989 C standard requires, and these work on all platforms with a standard C implementation.

Directive	Meaning	Example	Notes
%a	Weekday as locale's abbreviated name.	Sun, Mon, …, Sat (en_US); So, Mo, …, Sa (de_DE)	(1)
%A	Weekday as locale's full name.	Sunday, Monday, …, Saturday (en_US); Sonntag, Montag, …, Samstag (de_DE)	(1)
%w	Weekday as a decimal number, where 0 is Sunday and 6 is Saturday.	0, 1, …, 6	
%d	Day of the month as a zero-padded decimal number.	01, 02, …, 31	(9)
%b	Month as locale's abbreviated name.	Jan, Feb, …, Dec (en_US); Jan, Feb, …, Dez (de_DE)	(1)
%B	Month as locale's full name.	January, February, …, December (en_US); Januar, Februar, …, Dezember (de_DE)	(1)
%m	Month as a zero-padded decimal number.	01, 02, …, 12	(9)
%y	Year without century as a zero-padded decimal number.	00, 01, …, 99	(9)
%Y	Year with century as a decimal number.	0001, 0002, …, 2013, 2014, …, 9998, 9999	(2)
%H	Hour (24-hour clock) as a zero-padded decimal number.	00, 01, …, 23	(9)
%I	Hour (12-hour clock) as a zero-padded decimal number.	01, 02, …, 12	(9)
%p	Locale's equivalent of either AM or PM.	AM, PM (en_US); am, pm (de_DE)	(1), (3)
%M	Minute as a zero-padded decimal number.	00, 01, …, 59	(9)
%S	Second as a zero-padded decimal number.	00, 01, …, 59	(4), (9)
%f	Microsecond as a decimal number, zero-padded to 6 digits.	000000, 000001, …, 999999	(5)
%z	UTC offset in the form ±HHMM[SS[.ffffff]] (empty string if the object is naive).	(empty), +0000, -0400, +1030, +063415, -030712.345216	(6)
%Z	Time zone name (empty	(empty), UTC, GMT	(6)

Several additional directives not required by the C89 standard are included for convenience. These parameters all correspond to ISO 8601 date values.

Directive	Meaning	Example	Notes
`%G`	ISO 8601 year with century representing the year that contains the greater part of the ISO week (`%V`).	0001, 0002, …, 2013, 2014, …, 9998, 9999	(8)
`%u`	ISO 8601 weekday as a decimal number where 1 is Monday.	1, 2, …, 7	
`%V`	ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4.	01, 02, …, 53	(8), (9)
`%:z`	UTC offset in the form `±HH:MM[:SS[.ffffff]]` (empty string if the object is naive).	(empty), +00:00, -04:00, +10:30, +06:34:15, -03:07:12.345216	(6)

These may not be available on all platforms when used with the *strftime()* method. The ISO 8601 year and ISO 8601 week directives are not interchangeable with the year and week number directives above. Calling *strptime()* with incomplete or ambiguous ISO 8601 directives will raise a *ValueError*.

The full set of format codes supported varies across platforms, because Python calls the platform C library's `strftime()` function, and platform variations are common. To see the full set of format codes supported on your platform, consult the *strftime(3)* documentation. There are also differences between platforms in handling of unsupported format specifiers.

Added in version 3.6: `%G`, `%u` and `%V` were added.

Added in version 3.12: `%:z` was added.

Technical Detail

Broadly speaking, `d.strftime(fmt)` acts like the *time* module's `time.strftime(fmt, d.timetuple())` although not all objects support a *timetuple()* method.

For the *datetime.strptime()* class method, the default value is `1900-01-01T00:00:00.000`: any components not specified in the format string will be pulled from the default value.[4]

Using `datetime.strptime(date_string, format)` is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

except when the format includes sub-second components or time zone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

For *time* objects, the format codes for year, month, and day should not be used, as `time` objects have no such values. If they're used anyway, 1900 is substituted for the year, and 1 for the month and day.

For *date* objects, the format codes for hours, minutes, seconds, and microseconds should not be used, as *date* objects have no such values. If they're used anyway, 0 is substituted for them.

For the same reason, handling of format strings containing Unicode code points that can't be represented in the charset of the current locale is also platform-dependent. On some platforms such code points are preserved intact in the output, while on others `strftime` may raise *UnicodeError* or return an empty string instead.

Notes:

(1) Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, "month/day/year" versus "day/month/year"), and the output may contain non-ASCII characters.

(2) The *strptime()* method can parse years in the full [1, 9999] range, but years < 1000 must be zero-filled to 4-digit width.

Changed in version 3.2: In previous versions, *strftime()* method was restricted to years >= 1900.

[4] Passing `datetime.strptime('Feb 29', '%b %d')` will fail since 1900 is not a leap year.

Changed in version 3.3: In version 3.2, *strftime()* method was restricted to years >= 1000.

(3) When used with the *strptime()* method, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.

(4) Unlike the *time* module, the `datetime` module does not support leap seconds.

(5) When used with the *strptime()* method, the `%f` directive accepts from one to six digits and zero pads on the right. `%f` is an extension to the set of format characters in the C standard (but implemented separately in datetime objects, and therefore always available).

(6) For a naive object, the `%z`, `%:z` and `%Z` format codes are replaced by empty strings.

For an aware object:

%z

utcoffset() is transformed into a string of the form `±HHMM[SS[.ffffff]]`, where `HH` is a 2-digit string giving the number of UTC offset hours, `MM` is a 2-digit string giving the number of UTC offset minutes, `SS` is a 2-digit string giving the number of UTC offset seconds and `ffffff` is a 6-digit string giving the number of UTC offset microseconds. The `ffffff` part is omitted when the offset is a whole number of seconds and both the `ffffff` and the `SS` part is omitted when the offset is a whole number of minutes. For example, if *utcoffset()* returns `timedelta(hours=-3, minutes=-30)`, `%z` is replaced with the string `'-0330'`.

Changed in version 3.7: The UTC offset is not restricted to a whole number of minutes.

Changed in version 3.7: When the `%z` directive is provided to the *strptime()* method, the UTC offsets can have a colon as a separator between hours, minutes and seconds. For example, `'+01:00:00'` will be parsed as an offset of one hour. In addition, providing `'Z'` is identical to `'+00:00'`.

%:z

Behaves exactly as `%z`, but has a colon separator added between hours, minutes and seconds.

%Z

In *strftime()*, `%Z` is replaced by an empty string if *tzname()* returns `None`; otherwise `%Z` is replaced by the returned value, which must be a string.

strptime() only accepts certain values for `%Z`:

1. any value in `time.tzname` for your machine's locale
2. the hard-coded values `UTC` and `GMT`

So someone living in Japan may have `JST`, `UTC`, and `GMT` as valid values, but probably not `EST`. It will raise `ValueError` for invalid values.

Changed in version 3.2: When the `%z` directive is provided to the *strptime()* method, an aware *datetime* object will be produced. The `tzinfo` of the result will be set to a *timezone* instance.

(7) When used with the *strptime()* method, `%U` and `%W` are only used in calculations when the day of the week and the calendar year (`%Y`) are specified.

(8) Similar to `%U` and `%W`, `%V` is only used in calculations when the day of the week and the ISO year (`%G`) are specified in a *strptime()* format string. Also note that `%G` and `%Y` are not interchangeable.

(9) When used with the *strptime()* method, the leading zero is optional for formats `%d`, `%m`, `%H`, `%I`, `%M`, `%S`, `%j`, `%U`, `%W`, and `%V`. Format `%y` does require a leading zero.

(10) When parsing a month and day using *strptime()*, always include a year in the format. If the value you need to parse lacks a year, append an explicit dummy leap year. Otherwise your code will raise an exception when it encounters leap day because the default year used by the parser is not a leap year. Users run into this bug every four years…

```
>>> month_day = "02/29"
>>> datetime.strptime(f"{month_day};1984", "%m/%d;%Y")  # No leap year bug.
datetime.datetime(1984, 2, 29, 0, 0)
```

Deprecated since version 3.13, will be removed in version 3.15: *strptime()* calls using a format string containing a day of month without a year now emit a *DeprecationWarning*. In 3.15 or later we may change this into an error or change the default year to a leap year. See gh-70647.

8.2 zoneinfo — IANA time zone support

Added in version 3.9.

Source code: Lib/zoneinfo

The *zoneinfo* module provides a concrete time zone implementation to support the IANA time zone database as originally specified in **PEP 615**. By default, *zoneinfo* uses the system's time zone data if available; if no system time zone data is available, the library will fall back to using the first-party tzdata package available on PyPI.

See also

Module: *datetime*
Provides the *time* and *datetime* types with which the *ZoneInfo* class is designed to be used.

Package tzdata
First-party package maintained by the CPython core developers to supply time zone data via PyPI.

Availability: not WASI.

This module does not work or is not available on WebAssembly. See *WebAssembly platforms* for more information.

8.2.1 Using ZoneInfo

ZoneInfo is a concrete implementation of the *datetime.tzinfo* abstract base class, and is intended to be attached to `tzinfo`, either via the constructor, the *datetime.replace* method or *datetime.astimezone*:

```
>>> from zoneinfo import ZoneInfo
>>> from datetime import datetime, timedelta

>>> dt = datetime(2020, 10, 31, 12, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-10-31 12:00:00-07:00

>>> dt.tzname()
'PDT'
```

Datetimes constructed in this way are compatible with datetime arithmetic and handle daylight saving time transitions with no further intervention:

```
>>> dt_add = dt + timedelta(days=1)

>>> print(dt_add)
2020-11-01 12:00:00-08:00

>>> dt_add.tzname()
'PST'
```

These time zones also support the *fold* attribute introduced in **PEP 495**. During offset transitions which induce ambiguous times (such as a daylight saving time to standard time transition), the offset from *before* the transition is used when `fold=0`, and the offset *after* the transition is used when `fold=1`, for example:

```
>>> dt = datetime(2020, 11, 1, 1, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-11-01 01:00:00-07:00

>>> print(dt.replace(fold=1))
2020-11-01 01:00:00-08:00
```

When converting from another time zone, the fold will be set to the correct value:

```
>>> from datetime import timezone
>>> LOS_ANGELES = ZoneInfo("America/Los_Angeles")
>>> dt_utc = datetime(2020, 11, 1, 8, tzinfo=timezone.utc)

>>> # Before the PDT -> PST transition
>>> print(dt_utc.astimezone(LOS_ANGELES))
2020-11-01 01:00:00-07:00

>>> # After the PDT -> PST transition
>>> print((dt_utc + timedelta(hours=1)).astimezone(LOS_ANGELES))
2020-11-01 01:00:00-08:00
```

8.2.2 Data sources

The `zoneinfo` module does not directly provide time zone data, and instead pulls time zone information from the system time zone database or the first-party PyPI package tzdata, if available. Some systems, including notably Windows systems, do not have an IANA database available, and so for projects targeting cross-platform compatibility that require time zone data, it is recommended to declare a dependency on tzdata. If neither system data nor tzdata are available, all calls to *`ZoneInfo`* will raise *`ZoneInfoNotFoundError`*.

Configuring the data sources

When `ZoneInfo(key)` is called, the constructor first searches the directories specified in *`TZPATH`* for a file matching `key`, and on failure looks for a match in the tzdata package. This behavior can be configured in three ways:

1. The default *`TZPATH`* when not otherwise specified can be configured at *compile time*.
2. *`TZPATH`* can be configured using *an environment variable*.
3. At *runtime*, the search path can be manipulated using the *`reset_tzpath()`* function.

Compile-time configuration

The default *`TZPATH`* includes several common deployment locations for the time zone database (except on Windows, where there are no "well-known" locations for time zone data). On POSIX systems, downstream distributors and those building Python from source who know where their system time zone data is deployed may change the default time zone path by specifying the compile-time option `TZPATH` (or, more likely, the `configure flag --with-tzpath`), which should be a string delimited by *`os.pathsep`*.

On all platforms, the configured value is available as the `TZPATH` key in *`sysconfig.get_config_var()`*.

Environment configuration

When initializing *`TZPATH`* (either at import time or whenever *`reset_tzpath()`* is called with no arguments), the `zoneinfo` module will use the environment variable `PYTHONTZPATH`, if it exists, to set the search path.

`PYTHONTZPATH`

This is an *`os.pathsep`*-separated string containing the time zone search path to use. It must consist of only absolute rather than relative paths. Relative components specified in `PYTHONTZPATH` will not be used, but

otherwise the behavior when a relative path is specified is implementation-defined; CPython will raise *InvalidTZPathWarning*, but other implementations are free to silently ignore the erroneous component or raise an exception.

To set the system to ignore the system data and use the tzdata package instead, set `PYTHONTZPATH=""`.

Runtime configuration

The TZ search path can also be configured at runtime using the *reset_tzpath()* function. This is generally not an advisable operation, though it is reasonable to use it in test functions that require the use of a specific time zone path (or require disabling access to the system time zones).

8.2.3 The `ZoneInfo` class

class zoneinfo.**ZoneInfo**(*key*)

A concrete *datetime.tzinfo* subclass that represents an IANA time zone specified by the string `key`. Calls to the primary constructor will always return objects that compare identically; put another way, barring cache invalidation via *ZoneInfo.clear_cache()*, for all values of `key`, the following assertion will always be true:

```
a = ZoneInfo(key)
b = ZoneInfo(key)
assert a is b
```

`key` must be in the form of a relative, normalized POSIX path, with no up-level references. The constructor will raise *ValueError* if a non-conforming key is passed.

If no file matching `key` is found, the constructor will raise *ZoneInfoNotFoundError*.

The `ZoneInfo` class has two alternate constructors:

classmethod ZoneInfo.**from_file**(*fobj*, */*, *key=None*)

Constructs a `ZoneInfo` object from a file-like object returning bytes (e.g. a file opened in binary mode or an *io.BytesIO* object). Unlike the primary constructor, this always constructs a new object.

The `key` parameter sets the name of the zone for the purposes of `__str__()` and `__repr__()`.

Objects created via this constructor cannot be pickled (see *pickling*).

classmethod ZoneInfo.**no_cache**(*key*)

An alternate constructor that bypasses the constructor's cache. It is identical to the primary constructor, but returns a new object on each call. This is most likely to be useful for testing or demonstration purposes, but it can also be used to create a system with a different cache invalidation strategy.

Objects created via this constructor will also bypass the cache of a deserializing process when unpickled.

> **Caution**
>
> Using this constructor may change the semantics of your datetimes in surprising ways, only use it if you know that you need to.

The following class methods are also available:

classmethod ZoneInfo.**clear_cache**(**, only_keys=None*)

A method for invalidating the cache on the `ZoneInfo` class. If no arguments are passed, all caches are invalidated and the next call to the primary constructor for each key will return a new instance.

If an iterable of key names is passed to the `only_keys` parameter, only the specified keys will be removed from the cache. Keys passed to `only_keys` but not found in the cache are ignored.

> **Warning**
>
> Invoking this function may change the semantics of datetimes using `ZoneInfo` in surprising ways; this modifies module state and thus may have wide-ranging effects. Only use it if you know that you need to.

The class has one attribute:

`ZoneInfo.key`

This is a read-only *attribute* that returns the value of `key` passed to the constructor, which should be a lookup key in the IANA time zone database (e.g. `America/New_York`, `Europe/Paris` or `Asia/Tokyo`).

For zones constructed from file without specifying a `key` parameter, this will be set to `None`.

> **Note**
>
> Although it is a somewhat common practice to expose these to end users, these values are designed to be primary keys for representing the relevant zones and not necessarily user-facing elements. Projects like CLDR (the Unicode Common Locale Data Repository) can be used to get more user-friendly strings from these keys.

String representations

The string representation returned when calling *str* on a *ZoneInfo* object defaults to using the *ZoneInfo.key* attribute (see the note on usage in the attribute documentation):

```
>>> zone = ZoneInfo("Pacific/Kwajalein")
>>> str(zone)
'Pacific/Kwajalein'

>>> dt = datetime(2020, 4, 1, 3, 15, tzinfo=zone)
>>> f"{dt.isoformat()} [{dt.tzinfo}]"
'2020-04-01T03:15:00+12:00 [Pacific/Kwajalein]'
```

For objects constructed from a file without specifying a `key` parameter, `str` falls back to calling *repr()*. `ZoneInfo`'s `repr` is implementation-defined and not necessarily stable between versions, but it is guaranteed not to be a valid `ZoneInfo` key.

Pickle serialization

Rather than serializing all transition data, `ZoneInfo` objects are serialized by key, and `ZoneInfo` objects constructed from files (even those with a value for `key` specified) cannot be pickled.

The behavior of a `ZoneInfo` file depends on how it was constructed:

1. `ZoneInfo(key)`: When constructed with the primary constructor, a `ZoneInfo` object is serialized by key, and when deserialized, the deserializing process uses the primary and thus it is expected that these are expected to be the same object as other references to the same time zone. For example, if `europe_berlin_pkl` is a string containing a pickle constructed from `ZoneInfo("Europe/Berlin")`, one would expect the following behavior:

   ```
   >>> a = ZoneInfo("Europe/Berlin")
   >>> b = pickle.loads(europe_berlin_pkl)
   >>> a is b
   True
   ```

2. `ZoneInfo.no_cache(key)`: When constructed from the cache-bypassing constructor, the `ZoneInfo` object is also serialized by key, but when deserialized, the deserializing process uses the cache bypassing constructor. If `europe_berlin_pkl_nc` is a string containing a pickle constructed from `ZoneInfo.no_cache("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl_nc)
>>> a is b
False
```

3. `ZoneInfo.from_file(fobj, /, key=None)`: When constructed from a file, the `ZoneInfo` object raises an exception on pickling. If an end user wants to pickle a `ZoneInfo` constructed from a file, it is recommended that they use a wrapper type or a custom serialization function: either serializing by key or storing the contents of the file object and serializing that.

This method of serialization requires that the time zone data for the required key be available on both the serializing and deserializing side, similar to the way that references to classes and functions are expected to exist in both the serializing and deserializing environments. It also means that no guarantees are made about the consistency of results when unpickling a `ZoneInfo` pickled in an environment with a different version of the time zone data.

8.2.4 Functions

`zoneinfo.`**`available_timezones`**`()`

Get a set containing all the valid keys for IANA time zones available anywhere on the time zone path. This is recalculated on every call to the function.

This function only includes canonical zone names and does not include "special" zones such as those under the `posix/` and `right/` directories, or the `posixrules` zone.

Caution

This function may open a large number of files, as the best way to determine if a file on the time zone path is a valid time zone is to read the "magic string" at the beginning.

Note

These values are not designed to be exposed to end-users; for user facing elements, applications should use something like CLDR (the Unicode Common Locale Data Repository) to get more user-friendly strings. See also the cautionary note on *`ZoneInfo.key`*.

`zoneinfo.`**`reset_tzpath`**`(`*`to=None`*`)`

Sets or resets the time zone search path (*`TZPATH`*) for the module. When called with no arguments, *`TZPATH`* is set to the default value.

Calling `reset_tzpath` will not invalidate the *`ZoneInfo`* cache, and so calls to the primary `ZoneInfo` constructor will only use the new `TZPATH` in the case of a cache miss.

The `to` parameter must be a *sequence* of strings or *`os.PathLike`* and not a string, all of which must be absolute paths. *`ValueError`* will be raised if something other than an absolute path is passed.

8.2.5 Globals

`zoneinfo.`**`TZPATH`**

A read-only sequence representing the time zone search path – when constructing a `ZoneInfo` from a key, the key is joined to each entry in the `TZPATH`, and the first file found is used.

`TZPATH` may contain only absolute paths, never relative paths, regardless of how it is configured.

The object that `zoneinfo.TZPATH` points to may change in response to a call to *`reset_tzpath()`*, so it is recommended to use `zoneinfo.TZPATH` rather than importing `TZPATH` from `zoneinfo` or assigning a long-lived variable to `zoneinfo.TZPATH`.

For more information on configuring the time zone search path, see *Configuring the data sources*.

8.2.6 Exceptions and warnings

exception zoneinfo.**ZoneInfoNotFoundError**

Raised when construction of a *ZoneInfo* object fails because the specified key could not be found on the system. This is a subclass of *KeyError*.

exception zoneinfo.**InvalidTZPathWarning**

Raised when *PYTHONTZPATH* contains an invalid component that will be filtered out, such as a relative path.

8.3 calendar — General calendar-related functions

Source code: Lib/calendar.py

This module allows you to output calendars like the Unix **cal** program, and provides additional useful functions related to the calendar. By default, these calendars have Monday as the first day of the week, and Sunday as the last (the European convention). Use *setfirstweekday()* to set the first day of the week to Sunday (6) or to any other weekday. Parameters that specify dates are given as integers. For related functionality, see also the *datetime* and *time* modules.

The functions and classes defined in this module use an idealized calendar, the current Gregorian calendar extended indefinitely in both directions. This matches the definition of the "proleptic Gregorian" calendar in Dershowitz and Reingold's book "Calendrical Calculations", where it's the base calendar for all computations. Zero and negative years are interpreted as prescribed by the ISO 8601 standard. Year 0 is 1 BC, year -1 is 2 BC, and so on.

class calendar.**Calendar**(*firstweekday=0*)

Creates a *Calendar* object. *firstweekday* is an integer specifying the first day of the week. *MONDAY* is 0 (the default), *SUNDAY* is 6.

A *Calendar* object provides several methods that can be used for preparing the calendar data for formatting. This class doesn't do any formatting itself. This is the job of subclasses.

Calendar instances have the following methods and attributes:

firstweekday

The first weekday as an integer (0–6).

This property can also be set and read using *setfirstweekday()* and *getfirstweekday()* respectively.

getfirstweekday()

Return an *int* for the current first weekday (0–6).

Identical to reading the *firstweekday* property.

setfirstweekday(*firstweekday*)

Set the first weekday to *firstweekday*, passed as an *int* (0–6)

Identical to setting the *firstweekday* property.

iterweekdays()

Return an iterator for the week day numbers that will be used for one week. The first value from the iterator will be the same as the value of the *firstweekday* property.

itermonthdates(*year*, *month*)

Return an iterator for the month *month* (1–12) in the year *year*. This iterator will return all days (as *datetime.date* objects) for the month and all days before the start of the month or after the end of the month that are required to get a complete week.

itermonthdays(*year*, *month*)

Return an iterator for the month *month* in the year *year* similar to *itermonthdates()*, but not restricted by the *datetime.date* range. Days returned will simply be day of the month numbers. For the days outside of the specified month, the day number is 0.

itermonthdays2(*year*, *month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a day of the month number and a week day number.

itermonthdays3(*year*, *month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a year, a month and a day of the month numbers.

Added in version 3.7.

itermonthdays4(*year*, *month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a year, a month, a day of the month, and a day of the week numbers.

Added in version 3.7.

monthdatescalendar(*year*, *month*)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven `datetime.date` objects.

monthdays2calendar(*year*, *month*)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven tuples of day numbers and weekday numbers.

monthdayscalendar(*year*, *month*)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven day numbers.

yeardatescalendar(*year*, *width=3*)

Return the data for the specified year ready for formatting. The return value is a list of month rows. Each month row contains up to *width* months (defaulting to 3). Each month contains between 4 and 6 weeks and each week contains 1–7 days. Days are `datetime.date` objects.

yeardays2calendar(*year*, *width=3*)

Return the data for the specified year ready for formatting (similar to `yeardatescalendar()`). Entries in the week lists are tuples of day numbers and weekday numbers. Day numbers outside this month are zero.

yeardayscalendar(*year*, *width=3*)

Return the data for the specified year ready for formatting (similar to `yeardatescalendar()`). Entries in the week lists are day numbers. Day numbers outside this month are zero.

class calendar.**TextCalendar**(*firstweekday=0*)

This class can be used to generate plain text calendars.

`TextCalendar` instances have the following methods:

formatday(*theday*, *weekday*, *width*)

Return a string representing a single day formatted with the given *width*. If *theday* is `0`, return a string of spaces of the specified width, representing an empty day. The *weekday* parameter is unused.

formatweek(*theweek*, *w=0*)

Return a single week in a string with no newline. If *w* is provided, it specifies the width of the date columns, which are centered. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method.

formatweekday(*weekday*, *width*)

Return a string representing the name of a single weekday formatted to the specified *width*. The *weekday* parameter is an integer representing the day of the week, where `0` is Monday and `6` is Sunday.

formatweekheader(*width*)

Return a string containing the header row of weekday names, formatted with the given *width* for each column. The names depend on the locale settings and are padded to the specified width.

formatmonth(*theyear*, *themonth*, *w=0*, *l=0*)

Return a month's calendar in a multi-line string. If *w* is provided, it specifies the width of the date columns, which are centered. If *l* is given, it specifies the number of lines that each week will use. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method.

formatmonthname(*theyear*, *themonth*, *width=0*, *withyear=True*)

Return a string representing the month's name centered within the specified *width*. If *withyear* is `True`, include the year in the output. The *theyear* and *themonth* parameters specify the year and month for the name to be formatted respectively.

prmonth(*theyear*, *themonth*, *w=0*, *l=0*)

Print a month's calendar as returned by `formatmonth()`.

formatyear(*theyear*, *w=2*, *l=1*, *c=6*, *m=3*)

Return a *m*-column calendar for an entire year as a multi-line string. Optional parameters *w*, *l*, and *c* are for date column width, lines per week, and number of spaces between month columns, respectively. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method. The earliest year for which a calendar can be generated is platform-dependent.

pryear(*theyear*, *w=2*, *l=1*, *c=6*, *m=3*)

Print the calendar for an entire year as returned by `formatyear()`.

class calendar.**HTMLCalendar**(*firstweekday=0*)

This class can be used to generate HTML calendars.

`HTMLCalendar` instances have the following methods:

formatmonth(*theyear*, *themonth*, *withyear=True*)

Return a month's calendar as an HTML table. If *withyear* is true the year will be included in the header, otherwise just the month name will be used.

formatyear(*theyear*, *width=3*)

Return a year's calendar as an HTML table. *width* (defaulting to 3) specifies the number of months per row.

formatyearpage(*theyear*, *width=3*, *css='calendar.css'*, *encoding=None*)

Return a year's calendar as a complete HTML page. *width* (defaulting to 3) specifies the number of months per row. *css* is the name for the cascading style sheet to be used. `None` can be passed if no style sheet should be used. *encoding* specifies the encoding to be used for the output (defaulting to the system default encoding).

formatmonthname(*theyear*, *themonth*, *withyear=True*)

Return a month name as an HTML table row. If *withyear* is true the year will be included in the row, otherwise just the month name will be used.

`HTMLCalendar` has the following attributes you can override to customize the CSS classes used by the calendar:

cssclasses

A list of CSS classes used for each weekday. The default class list is:

```
cssclasses = ["mon", "tue", "wed", "thu", "fri", "sat", "sun"]
```

more styles can be added for each day:

```
cssclasses = ["mon text-bold", "tue", "wed", "thu", "fri", "sat", "sun red
↪"]
```

Note that the length of this list must be seven items.

cssclass_noday

The CSS class for a weekday occurring in the previous or coming month.

Added in version 3.7.

cssclasses_weekday_head

A list of CSS classes used for weekday names in the header row. The default is the same as *cssclasses*.

Added in version 3.7.

cssclass_month_head

The month's head CSS class (used by *formatmonthname()*). The default value is `"month"`.

Added in version 3.7.

cssclass_month

The CSS class for the whole month's table (used by *formatmonth()*). The default value is `"month"`.

Added in version 3.7.

cssclass_year

The CSS class for the whole year's table of tables (used by *formatyear()*). The default value is `"year"`.

Added in version 3.7.

cssclass_year_head

The CSS class for the table head for the whole year (used by *formatyear()*). The default value is `"year"`.

Added in version 3.7.

Note that although the naming for the above described class attributes is singular (e.g. `cssclass_month` `cssclass_noday`), one can replace the single CSS class with a space separated list of CSS classes, for example:

```
"text-bold text-red"
```

Here is an example how `HTMLCalendar` can be customized:

```
class CustomHTMLCal(calendar.HTMLCalendar):
    cssclasses = [style + " text-nowrap" for style in
                  calendar.HTMLCalendar.cssclasses]
    cssclass_month_head = "text-center month-head"
    cssclass_month = "text-center month"
    cssclass_year = "text-italic lead"
```

class calendar.**LocaleTextCalendar**(*firstweekday=0*, *locale=None*)

This subclass of *TextCalendar* can be passed a locale name in the constructor and will return month and weekday names in the specified locale.

class calendar.**LocaleHTMLCalendar**(*firstweekday=0*, *locale=None*)

This subclass of *HTMLCalendar* can be passed a locale name in the constructor and will return month and weekday names in the specified locale.

Note

The constructor, `formatweekday()` and `formatmonthname()` methods of these two classes temporarily change the `LC_TIME` locale to the given *locale*. Because the current locale is a process-wide setting, they are not thread-safe.

For simple text calendars this module provides the following functions.

calendar.**setfirstweekday**(*weekday*)

Sets the weekday (`0` is Monday, `6` is Sunday) to start each week. The values *MONDAY*, *TUESDAY*, *WEDNESDAY*, *THURSDAY*, *FRIDAY*, *SATURDAY*, and *SUNDAY* are provided for convenience. For example, to set the first weekday to Sunday:

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

calendar.**firstweekday**()

Returns the current setting for the weekday to start each week.

calendar.**isleap**(*year*)

Returns *True* if *year* is a leap year, otherwise *False*.

calendar.**leapdays**(*y1*, *y2*)

Returns the number of leap years in the range from *y1* to *y2* (exclusive), where *y1* and *y2* are years.

This function works for ranges spanning a century change.

calendar.**weekday**(*year*, *month*, *day*)

Returns the day of the week (`0` is Monday) for *year* (`1970–…`), *month* (`1–12`), *day* (`1–31`).

calendar.**weekheader**(*n*)

Return a header containing abbreviated weekday names. *n* specifies the width in characters for one weekday.

calendar.**monthrange**(*year*, *month*)

Returns weekday of first day of the month and number of days in month, for the specified *year* and *month*.

calendar.**monthcalendar**(*year*, *month*)

Returns a matrix representing a month's calendar. Each row represents a week; days outside of the month are represented by zeros. Each week begins with Monday unless set by *setfirstweekday()*.

calendar.**prmonth**(*theyear*, *themonth*, *w=0*, *l=0*)

Prints a month's calendar as returned by *month()*.

calendar.**month**(*theyear*, *themonth*, *w=0*, *l=0*)

Returns a month's calendar in a multi-line string using the *formatmonth()* of the *TextCalendar* class.

calendar.**prcal**(*year*, *w=0*, *l=0*, *c=6*, *m=3*)

Prints the calendar for an entire year as returned by *calendar()*.

calendar.**calendar**(*year*, *w=2*, *l=1*, *c=6*, *m=3*)

Returns a 3-column calendar for an entire year as a multi-line string using the *formatyear()* of the *TextCalendar* class.

calendar.**timegm**(*tuple*)

An unrelated but handy function that takes a time tuple such as returned by the *gmtime()* function in the *time* module, and returns the corresponding Unix timestamp value, assuming an epoch of 1970, and the POSIX encoding. In fact, *time.gmtime()* and *timegm()* are each others' inverse.

The *calendar* module exports the following data attributes:

calendar.**day_name**

A sequence that represents the days of the week in the current locale, where Monday is day number 0.

```
>>> import calendar
>>> list(calendar.day_name)
['Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday', 'Saturday', 'Sunday']
```

calendar.**day_abbr**

A sequence that represents the abbreviated days of the week in the current locale, where Mon is day number 0.

```
>>> import calendar
>>> list(calendar.day_abbr)
['Mon', 'Tue', 'Wed', 'Thu', 'Fri', 'Sat', 'Sun']
```

calendar.**MONDAY**

calendar.**TUESDAY**

calendar.**WEDNESDAY**

calendar.**THURSDAY**

calendar.**FRIDAY**

calendar.**SATURDAY**

calendar.**SUNDAY**

Aliases for the days of the week, where `MONDAY` is `0` and `SUNDAY` is `6`.

Added in version 3.12.

class calendar.**Day**

Enumeration defining days of the week as integer constants. The members of this enumeration are exported to the module scope as *MONDAY* through *SUNDAY*.

Added in version 3.12.

calendar.**month_name**

A sequence that represents the months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_name[0]` is the empty string.

```
>>> import calendar
>>> list(calendar.month_name)
['', 'January', 'February', 'March', 'April', 'May', 'June', 'July', 'August',
↪'September', 'October', 'November', 'December']
```

calendar.**month_abbr**

A sequence that represents the abbreviated months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_abbr[0]` is the empty string.

```
>>> import calendar
>>> list(calendar.month_abbr)
['', 'Jan', 'Feb', 'Mar', 'Apr', 'May', 'Jun', 'Jul', 'Aug', 'Sep', 'Oct', 'Nov
↪', 'Dec']
```

calendar.**JANUARY**

calendar.**FEBRUARY**

calendar.**MARCH**

calendar.**APRIL**

calendar.**MAY**

calendar.**JUNE**

calendar.**JULY**

calendar.**AUGUST**

calendar.**SEPTEMBER**

calendar.**OCTOBER**

calendar.**NOVEMBER**

calendar.**DECEMBER**

Aliases for the months of the year, where `JANUARY` is `1` and `DECEMBER` is `12`.

Added in version 3.12.

class calendar.**Month**

Enumeration defining months of the year as integer constants. The members of this enumeration are exported to the module scope as *JANUARY* through *DECEMBER*.

Added in version 3.12.

The *calendar* module defines the following exceptions:

exception calendar.**IllegalMonthError**(*month*)

A subclass of *ValueError*, raised when the given month number is outside of the range 1-12 (inclusive).

month

The invalid month number.

exception calendar.**IllegalWeekdayError**(*weekday*)

A subclass of *ValueError*, raised when the given weekday number is outside of the range 0-6 (inclusive).

weekday

The invalid weekday number.

See also

Module *datetime*
Object-oriented interface to dates and times with similar functionality to the *time* module.

Module *time*
Low-level time related functions.

8.3.1 Command-Line Usage

Added in version 2.5.

The *calendar* module can be executed as a script from the command line to interactively print a calendar.

```
python -m calendar [-h] [-L LOCALE] [-e ENCODING] [-t {text,html}]
                   [-w WIDTH] [-l LINES] [-s SPACING] [-m MONTHS] [-c CSS]
                   [-f FIRST_WEEKDAY] [year] [month]
```

For example, to print a calendar for the year 2000:

```
$ python -m calendar 2000
                                  2000

      January                   February                  March

30 31
```

The following options are accepted:

--help, -h

Show the help message and exit.

--locale LOCALE, **-L** LOCALE

The locale to use for month and weekday names. Defaults to English.

--encoding ENCODING, **-e** ENCODING

The encoding to use for output. *--encoding* is required if *--locale* is set.

--type {text,html}, **-t** {text,html}

Print the calendar to the terminal as text, or as an HTML document.

--first-weekday FIRST_WEEKDAY, **-f** FIRST_WEEKDAY

The weekday to start each week. Must be a number between 0 (Monday) and 6 (Sunday). Defaults to 0.

Added in version 3.13.

year

The year to print the calendar for. Defaults to the current year.

month

The month of the specified *year* to print the calendar for. Must be a number between 1 and 12, and may only be used in text mode. Defaults to printing a calendar for the full year.

Text-mode options:

--width WIDTH, **-w** WIDTH

The width of the date column in terminal columns. The date is printed centred in the column. Any value lower than 2 is ignored. Defaults to 2.

--lines LINES, **-l** LINES

The number of lines for each week in terminal rows. The date is printed top-aligned. Any value lower than 1 is ignored. Defaults to 1.

--spacing SPACING, **-s** SPACING

The space between months in columns. Any value lower than 2 is ignored. Defaults to 6.

--months MONTHS, **-m** MONTHS

The number of months printed per row. Defaults to 3.

HTML-mode options:

--css CSS, **-c** CSS

The path of a CSS stylesheet to use for the calendar. This must either be relative to the generated HTML, or an absolute HTTP or `file:///` URL.

8.4 `collections` — Container datatypes

Source code: Lib/collections/__init__.py

This module implements specialized container datatypes providing alternatives to Python's general purpose built-in containers, *dict*, *list*, *set*, and *tuple*.

namedtuple()	factory function for creating tuple subclasses with named fields
deque	list-like container with fast appends and pops on either end
ChainMap	dict-like class for creating a single view of multiple mappings
Counter	dict subclass for counting *hashable* objects
OrderedDict	dict subclass that remembers the order entries were added
defaultdict	dict subclass that calls a factory function to supply missing values
UserDict	wrapper around dictionary objects for easier dict subclassing
UserList	wrapper around list objects for easier list subclassing
UserString	wrapper around string objects for easier string subclassing

8.4.1 `ChainMap` objects

Added in version 3.3.

A *ChainMap* class is provided for quickly linking a number of mappings so they can be treated as a single unit. It is often much faster than creating a new dictionary and running multiple *update()* calls.

The class can be used to simulate nested scopes and is useful in templating.

class collections.**ChainMap**(**maps*)

A *ChainMap* groups multiple dicts or other mappings together to create a single, updateable view. If no *maps* are specified, a single empty dictionary is provided so that a new chain always has at least one mapping.

The underlying mappings are stored in a list. That list is public and can be accessed or updated using the *maps* attribute. There is no other state.

Lookups search the underlying mappings successively until a key is found. In contrast, writes, updates, and deletions only operate on the first mapping.

A *ChainMap* incorporates the underlying mappings by reference. So, if one of the underlying mappings gets updated, those changes will be reflected in *ChainMap*.

All of the usual dictionary methods are supported. In addition, there is a *maps* attribute, a method for creating new subcontexts, and a property for accessing all but the first mapping:

maps

A user updateable list of mappings. The list is ordered from first-searched to last-searched. It is the only stored state and can be modified to change which mappings are searched. The list should always contain at least one mapping.

new_child(*m=None*, ***kwargs*)

Returns a new *ChainMap* containing a new map followed by all of the maps in the current instance. If `m` is specified, it becomes the new map at the front of the list of mappings; if not specified, an empty dict is used, so that a call to `d.new_child()` is equivalent to: `ChainMap({}, *d.maps)`. If any keyword arguments are specified, they update passed map or new empty dict. This method is used for creating subcontexts that can be updated without altering values in any of the parent mappings.

Changed in version 3.4: The optional `m` parameter was added.

Changed in version 3.10: Keyword arguments support was added.

parents

Property returning a new *ChainMap* containing all of the maps in the current instance except the first one. This is useful for skipping the first map in the search. Use cases are similar to those for the `nonlocal` keyword used in *nested scopes*. The use cases also parallel those for the built-in *super()* function. A reference to `d.parents` is equivalent to: `ChainMap(*d.maps[1:])`.

Note, the iteration order of a *ChainMap* is determined by scanning the mappings last to first:

```
>>> baseline = {'music': 'bach', 'art': 'rembrandt'}
>>> adjustments = {'art': 'van gogh', 'opera': 'carmen'}
>>> list(ChainMap(adjustments, baseline))
['music', 'art', 'opera']
```

This gives the same ordering as a series of *dict.update()* calls starting with the last mapping:

```
>>> combined = baseline.copy()
>>> combined.update(adjustments)
>>> list(combined)
['music', 'art', 'opera']
```

Changed in version 3.9: Added support for `|` and `|=` operators, specified in **PEP 584**.

See also

- The MultiContext class in the Enthought CodeTools package has options to support writing to any mapping in the chain.
- Django's Context class for templating is a read-only chain of mappings. It also features pushing and popping of contexts similar to the *new_child()* method and the *parents* property.
- The Nested Contexts recipe has options to control whether writes and other mutations apply only to the first mapping or to any mapping in the chain.
- A greatly simplified read-only version of Chainmap.

`ChainMap` Examples and Recipes

This section shows various approaches to working with chained maps.

Example of simulating Python's internal lookup chain:

```
import builtins
pylookup = ChainMap(locals(), globals(), vars(builtins))
```

Example of letting user specified command-line arguments take precedence over environment variables which in turn take precedence over default values:

```
import os, argparse

defaults = {'color': 'red', 'user': 'guest'}

parser = argparse.ArgumentParser()
parser.add_argument('-u', '--user')
parser.add_argument('-c', '--color')
namespace = parser.parse_args()
command_line_args = {k: v for k, v in vars(namespace).items() if v is not None}

combined = ChainMap(command_line_args, os.environ, defaults)
```

(continues on next page)

(continued from previous page)

```
print(combined['color'])
print(combined['user'])
```

Example patterns for using the *ChainMap* class to simulate nested contexts:

```
c = ChainMap()          # Create root context
d = c.new_child()       # Create nested child context
e = c.new_child()       # Child of c, independent from d
e.maps[0]               # Current context dictionary -- like Python's locals()
e.maps[-1]              # Root context -- like Python's globals()
e.parents               # Enclosing context chain -- like Python's nonlocals

d['x'] = 1              # Set value in current context
d['x']                  # Get first key in the chain of contexts
del d['x']              # Delete from current context
list(d)                 # All nested values
k in d                  # Check all nested values
len(d)                  # Number of nested values
d.items()               # All nested items
dict(d)                 # Flatten into a regular dictionary
```

The *ChainMap* class only makes updates (writes and deletions) to the first mapping in the chain while lookups will search the full chain. However, if deep writes and deletions are desired, it is easy to make a subclass that updates keys found deeper in the chain:

```
class DeepChainMap(ChainMap):
    'Variant of ChainMap that allows direct updates to inner scopes'

    def __setitem__(self, key, value):
        for mapping in self.maps:
            if key in mapping:
                mapping[key] = value
                return
        self.maps[0][key] = value

    def __delitem__(self, key):
        for mapping in self.maps:
            if key in mapping:
                del mapping[key]
                return
        raise KeyError(key)

>>> d = DeepChainMap({'zebra': 'black'}, {'elephant': 'blue'}, {'lion': 'yellow'})
>>> d['lion'] = 'orange'         # update an existing key two levels down
>>> d['snake'] = 'red'           # new keys get added to the topmost dict
>>> del d['elephant']            # remove an existing key one level down
>>> d                            # display result
DeepChainMap({'zebra': 'black', 'snake': 'red'}, {}, {'lion': 'orange'})
```

8.4.2 `Counter` objects

A counter tool is provided to support convenient and rapid tallies. For example:

```
>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
```

(continues on next page)

(continued from previous page)

```
...     cnt[word] += 1
...
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554),  ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]
```

class collections.**Counter**([*iterable-or-mapping*])

A *Counter* is a *dict* subclass for counting *hashable* objects. It is a collection where elements are stored as dictionary keys and their counts are stored as dictionary values. Counts are allowed to be any integer value including zero or negative counts. The *Counter* class is similar to bags or multisets in other languages.

Elements are counted from an *iterable* or initialized from another *mapping* (or counter):

```
>>> c = Counter()                           # a new, empty counter
>>> c = Counter('gallahad')                 # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2})      # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8)             # a new counter from keyword args
```

Counter objects have a dictionary interface except that they return a zero count for missing items instead of raising a *KeyError*:

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon']                              # count of a missing element is␣
↪zero
0
```

Setting a count to zero does not remove an element from a counter. Use `del` to remove it entirely:

```
>>> c['sausage'] = 0                        # counter entry with a zero count
>>> del c['sausage']                        # del actually removes the entry
```

Added in version 3.1.

Changed in version 3.7: As a *dict* subclass, *Counter* inherited the capability to remember insertion order. Math operations on *Counter* objects also preserve order. Results are ordered according to when an element is first encountered in the left operand and then by the order encountered in the right operand.

Counter objects support additional methods beyond those available for all dictionaries:

elements()

Return an iterator over elements repeating each as many times as its count. Elements are returned in the order first encountered. If an element's count is less than one, *elements()* will ignore it.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> sorted(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

most_common([*n*])

Return a list of the *n* most common elements and their counts from the most common to the least. If *n* is omitted or `None`, *most_common()* returns *all* elements in the counter. Elements with equal counts are ordered in the order first encountered:

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('b', 2), ('r', 2)]
```

subtract(*[iterable-or-mapping]*)

Elements are subtracted from an *iterable* or from another *mapping* (or counter). Like `dict.update()` but subtracts counts instead of replacing them. Both inputs and outputs may be zero or negative.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

Added in version 3.2.

total()

Compute the sum of the counts.

```
>>> c = Counter(a=10, b=5, c=0)
>>> c.total()
15
```

Added in version 3.10.

The usual dictionary methods are available for `Counter` objects except for two which work differently for counters.

fromkeys(*iterable*)

This class method is not implemented for `Counter` objects.

update(*[iterable-or-mapping]*)

Elements are counted from an *iterable* or added-in from another *mapping* (or counter). Like `dict.update()` but adds counts instead of replacing them. Also, the *iterable* is expected to be a sequence of elements, not a sequence of `(key, value)` pairs.

Counters support rich comparison operators for equality, subset, and superset relationships: `==`, `!=`, `<`, `<=`, `>`, `>=`. All of those tests treat missing elements as having zero counts so that `Counter(a=1) == Counter(a=1, b=0)` returns true.

Changed in version 3.10: Rich comparison operations were added.

Changed in version 3.10: In equality tests, missing elements are treated as having zero counts. Formerly, `Counter(a=3)` and `Counter(a=3, b=0)` were considered distinct.

Common patterns for working with `Counter` objects:

```
c.total()                       # total of all counts
c.clear()                       # reset all counts
list(c)                         # list unique elements
set(c)                          # convert to a set
dict(c)                         # convert to a regular dictionary
c.items()                       # access the (elem, cnt) pairs
Counter(dict(list_of_pairs))    # convert from a list of (elem, cnt) pairs
c.most_common()[:-n-1:-1]       # n least common elements
+c                              # remove zero and negative counts
```

Several mathematical operations are provided for combining `Counter` objects to produce multisets (counters that have counts greater than zero). Addition and subtraction combine counters by adding or subtracting the counts of corresponding elements. Intersection and union return the minimum and maximum of corresponding counts. Equality and inclusion compare corresponding counts. Each operation can accept inputs with signed counts, but the output will exclude results with counts of zero or less.

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                       # add two counters together:  c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d                       # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d                       # intersection:  min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d                       # union:  max(c[x], d[x])
Counter({'a': 3, 'b': 2})
>>> c == d                      # equality:  c[x] == d[x]
False
>>> c <= d                      # inclusion:  c[x] <= d[x]
False
```

Unary addition and subtraction are shortcuts for adding an empty counter or subtracting from an empty counter.

```
>>> c = Counter(a=2, b=-4)
>>> +c
Counter({'a': 2})
>>> -c
Counter({'b': 4})
```

Added in version 3.3: Added support for unary plus, unary minus, and in-place multiset operations.

Note

Counters were primarily designed to work with positive integers to represent running counts; however, care was taken to not unnecessarily preclude use cases needing other types or negative values. To help with those use cases, this section documents the minimum range and type restrictions.

- The `Counter` class itself is a dictionary subclass with no restrictions on its keys and values. The values are intended to be numbers representing counts, but you *could* store anything in the value field.
- The `most_common()` method requires only that the values be orderable.
- For in-place operations such as `c[key] += 1`, the value type need only support addition and subtraction. So fractions, floats, and decimals would work and negative values are supported. The same is also true for `update()` and `subtract()` which allow negative and zero values for both inputs and outputs.
- The multiset methods are designed only for use cases with positive values. The inputs may be negative or zero, but only outputs with positive values are created. There are no type restrictions, but the value type needs to support addition, subtraction, and comparison.
- The `elements()` method requires integer counts. It ignores zero and negative counts.

```

8.4.3 deque objects

class collections.**deque**([*iterable*[, *maxlen*]])

Returns a new deque object initialized left-to-right (using *append()*) with data from *iterable*. If *iterable* is not specified, the new deque is empty.

Deques are a generalization of stacks and queues (the name is pronounced "deck" and is short for "double-ended queue"). Deques support thread-safe, memory efficient appends and pops from either side of the deque with approximately the same $O(1)$ performance in either direction.

Though *list* objects support similar operations, they are optimized for fast fixed-length operations and incur $O(n)$ memory movement costs for `pop(0)` and `insert(0, v)` operations which change both the size and position of the underlying data representation.

If *maxlen* is not specified or is `None`, deques may grow to an arbitrary length. Otherwise, the deque is bounded to the specified maximum length. Once a bounded length deque is full, when new items are added, a corresponding number of items are discarded from the opposite end. Bounded length deques provide functionality similar to the `tail` filter in Unix. They are also useful for tracking transactions and other pools of data where only the most recent activity is of interest.

Deque objects support the following methods:

append(*x*)

Add *x* to the right side of the deque.

appendleft(*x*)

Add *x* to the left side of the deque.

clear()

Remove all elements from the deque leaving it with length 0.

copy()

Create a shallow copy of the deque.

Added in version 3.5.

count(*x*)

Count the number of deque elements equal to *x*.

Added in version 3.2.

extend(*iterable*)

Extend the right side of the deque by appending elements from the iterable argument.

extendleft(*iterable*)

Extend the left side of the deque by appending elements from *iterable*. Note, the series of left appends results in reversing the order of elements in the iterable argument.

index(*x*[, *start*[, *stop*]])

Return the position of *x* in the deque (at or after index *start* and before index *stop*). Returns the first match or raises *ValueError* if not found.

Added in version 3.5.

insert(*i*, *x*)

Insert *x* into the deque at position *i*.

If the insertion would cause a bounded deque to grow beyond *maxlen*, an *IndexError* is raised.

Added in version 3.5.

pop()

Remove and return an element from the right side of the deque. If no elements are present, raises an *IndexError*.

popleft()

Remove and return an element from the left side of the deque. If no elements are present, raises an *IndexError*.

remove(*value*)

Remove the first occurrence of *value*. If not found, raises a *ValueError*.

reverse()

Reverse the elements of the deque in-place and then return `None`.

Added in version 3.2.

rotate(*n=1*)

Rotate the deque *n* steps to the right. If *n* is negative, rotate to the left.

When the deque is not empty, rotating one step to the right is equivalent to `d.appendleft(d.pop())`, and rotating one step to the left is equivalent to `d.append(d.popleft())`.

Deque objects also provide one read-only attribute:

maxlen

Maximum size of a deque or `None` if unbounded.

Added in version 3.1.

In addition to the above, deques support iteration, pickling, `len(d)`, `reversed(d)`, `copy.copy(d)`, `copy.deepcopy(d)`, membership testing with the `in` operator, and subscript references such as `d[0]` to access the first element. Indexed access is $O(1)$ at both ends but slows to $O(n)$ in the middle. For fast random access, use lists instead.

Starting in version 3.5, deques support `__add__()`, `__mul__()`, and `__imul__()`.

Example:

```
>>> from collections import deque
>>> d = deque('ghi')                 # make a new deque with three items
>>> for elem in d:                   # iterate over the deque's elements
...     print(elem.upper())
G
H
I

>>> d.append('j')                    # add a new entry to the right side
>>> d.appendleft('f')                # add a new entry to the left side
>>> d                                # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                          # return and remove the rightmost item
'j'
>>> d.popleft()                      # return and remove the leftmost item
'f'
>>> list(d)                          # list the contents of the deque
['g', 'h', 'i']
>>> d[0]                             # peek at leftmost item
'g'
>>> d[-1]                            # peek at rightmost item
'i'

>>> list(reversed(d))                # list the contents of a deque in reverse
```

(continues on next page)

(continued from previous page)

```
['i', 'h', 'g']
>>> 'h' in d                            # search the deque
True
>>> d.extend('jkl')                     # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)                         # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)                        # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))                  # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                           # empty the deque
>>> d.pop()                             # cannot pop from an empty deque
Traceback (most recent call last):
    File "<pyshell#6>", line 1, in -toplevel-
        d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc')                 # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])
```

deque Recipes

This section shows various approaches to working with deques.

Bounded length deques provide functionality similar to the `tail` filter in Unix:

```
def tail(filename, n=10):
    'Return the last n lines of a file'
    with open(filename) as f:
        return deque(f, n)
```

Another approach to using deques is to maintain a sequence of recently added elements by appending to the right and popping to the left:

```
def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # https://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / n
```

A round-robin scheduler can be implemented with input iterators stored in a *deque*. Values are yielded from the active iterator in position zero. If that iterator is exhausted, it can be removed with *popleft()*; otherwise, it can be cycled back to the end with the *rotate()* method:

```
def roundrobin(*iterables):
    "roundrobin('ABC', 'D', 'EF') --> A D E B F C"
    iterators = deque(map(iter, iterables))
    while iterators:
        try:
            while True:
                yield next(iterators[0])
                iterators.rotate(-1)
        except StopIteration:
            # Remove an exhausted iterator.
            iterators.popleft()
```

The *rotate()* method provides a way to implement *deque* slicing and deletion. For example, a pure Python implementation of `del d[n]` relies on the `rotate()` method to position elements to be popped:

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

To implement *deque* slicing, use a similar approach applying *rotate()* to bring a target element to the left side of the deque. Remove old entries with *popleft()*, add new entries with *extend()*, and then reverse the rotation. With minor variations on that approach, it is easy to implement Forth style stack manipulations such as `dup`, `drop`, `swap`, `over`, `pick`, `rot`, and `roll`.

8.4.4 `defaultdict` objects

class collections.**defaultdict**(*default_factory=None*, */*[, ...])

Return a new dictionary-like object. *defaultdict* is a subclass of the built-in *dict* class. It overrides one method and adds one writable instance variable. The remaining functionality is the same as for the *dict* class and is not documented here.

The first argument provides the initial value for the *default_factory* attribute; it defaults to `None`. All remaining arguments are treated the same as if they were passed to the *dict* constructor, including keyword arguments.

defaultdict objects support the following method in addition to the standard *dict* operations:

__missing__(*key*)

If the *default_factory* attribute is `None`, this raises a *KeyError* exception with the *key* as argument.

If *default_factory* is not `None`, it is called without arguments to provide a default value for the given *key*, this value is inserted in the dictionary for the *key*, and returned.

If calling *default_factory* raises an exception this exception is propagated unchanged.

This method is called by the `__getitem__()` method of the *dict* class when the requested key is not found; whatever it returns or raises is then returned or raised by `__getitem__()`.

Note that *__missing__()* is *not* called for any operations besides `__getitem__()`. This means that *get()* will, like normal dictionaries, return `None` as a default rather than using *default_factory*.

defaultdict objects support the following instance variable:

default_factory

This attribute is used by the *__missing__()* method; it is initialized from the first argument to the constructor, if present, or to `None`, if absent.

Changed in version 3.9: Added merge (`|`) and update (`|=`) operators, specified in **PEP 584**.

`defaultdict` Examples

Using *`list`* as the *`default_factory`*, it is easy to group a sequence of key-value pairs into a dictionary of lists:

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

When each key is encountered for the first time, it is not already in the mapping; so an entry is automatically created using the *`default_factory`* function which returns an empty *`list`*. The `list.append()` operation then attaches the value to the new list. When keys are encountered again, the look-up proceeds normally (returning the list for that key) and the `list.append()` operation adds another value to the list. This technique is simpler and faster than an equivalent technique using *`dict.setdefault()`*:

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

Setting the *`default_factory`* to *`int`* makes the *`defaultdict`* useful for counting (like a bag or multiset in other languages):

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> sorted(d.items())
[('i', 4), ('m', 1), ('p', 2), ('s', 4)]
```

When a letter is first encountered, it is missing from the mapping, so the *`default_factory`* function calls *`int()`* to supply a default count of zero. The increment operation then builds up the count for each letter.

The function *`int()`* which always returns zero is just a special case of constant functions. A faster and more flexible way to create constant functions is to use a lambda function which can supply any constant value (not just zero):

```
>>> def constant_factory(value):
...     return lambda: value
...
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

Setting the *`default_factory`* to *`set`* makes the *`defaultdict`* useful for building a dictionary of sets:

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> sorted(d.items())
[('blue', {2, 4}), ('red', {1, 3})]
```

8.4.5 `namedtuple()` Factory Function for Tuples with Named Fields

Named tuples assign meaning to each position in a tuple and allow for more readable, self-documenting code. They can be used wherever regular tuples are used, and they add the ability to access fields by name instead of position index.

`collections.`**`namedtuple`**(*typename*, *field_names*, *, *rename=False*, *defaults=None*, *module=None*)

Returns a new tuple subclass named *typename*. The new subclass is used to create tuple-like objects that have fields accessible by attribute lookup as well as being indexable and iterable. Instances of the subclass also have a helpful docstring (with *typename* and *field_names*) and a helpful `__repr__()` method which lists the tuple contents in a `name=value` format.

The *field_names* are a sequence of strings such as `['x', 'y']`. Alternatively, *field_names* can be a single string with each fieldname separated by whitespace and/or commas, for example `'x y'` or `'x, y'`.

Any valid Python identifier may be used for a fieldname except for names starting with an underscore. Valid identifiers consist of letters, digits, and underscores but do not start with a digit or underscore and cannot be a *keyword* such as *class*, *for*, *return*, *global*, *pass*, or *raise*.

If *rename* is true, invalid fieldnames are automatically replaced with positional names. For example, `['abc', 'def', 'ghi', 'abc']` is converted to `['abc', '_1', 'ghi', '_3']`, eliminating the keyword `def` and the duplicate fieldname `abc`.

defaults can be `None` or an *iterable* of default values. Since fields with a default value must come after any fields without a default, the *defaults* are applied to the rightmost parameters. For example, if the fieldnames are `['x', 'y', 'z']` and the defaults are `(1, 2)`, then `x` will be a required argument, `y` will default to `1`, and `z` will default to `2`.

If *module* is defined, the `__module__` attribute of the named tuple is set to that value.

Named tuple instances do not have per-instance dictionaries, so they are lightweight and require no more memory than regular tuples.

To support pickling, the named tuple class should be assigned to a variable that matches *typename*.

Changed in version 3.1: Added support for *rename*.

Changed in version 3.6: The *verbose* and *rename* parameters became *keyword-only arguments*.

Changed in version 3.6: Added the *module* parameter.

Changed in version 3.7: Removed the *verbose* parameter and the `_source` attribute.

Changed in version 3.7: Added the *defaults* parameter and the `_field_defaults` attribute.

```
>>> # Basic example
>>> Point = namedtuple('Point', ['x', 'y'])
>>> p = Point(11, y=22)     # instantiate with positional or keyword arguments
>>> p[0] + p[1]             # indexable like the plain tuple (11, 22)
33
>>> x, y = p                # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y               # fields also accessible by name
33
>>> p                       # readable __repr__ with a name=value style
Point(x=11, y=22)
```

Named tuples are especially useful for assigning field names to result tuples returned by the *csv* or *sqlite3* modules:

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department,␣
↪paygrade')

import csv
```

(continues on next page)

(continued from previous page)

```
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
    print(emp.name, emp.title)

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print(emp.name, emp.title)
```

In addition to the methods inherited from tuples, named tuples support three additional methods and two attributes. To prevent conflicts with field names, the method and attribute names start with an underscore.

classmethod somenamedtuple.**_make**(*iterable*)

Class method that makes a new instance from an existing sequence or iterable.

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

somenamedtuple.**_asdict**()

Return a new *dict* which maps field names to their corresponding values:

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
{'x': 11, 'y': 22}
```

Changed in version 3.1: Returns an *OrderedDict* instead of a regular *dict*.

Changed in version 3.8: Returns a regular *dict* instead of an *OrderedDict*. As of Python 3.7, regular dicts are guaranteed to be ordered. If the extra features of *OrderedDict* are required, the suggested remediation is to cast the result to the desired type: `OrderedDict(nt._asdict())`.

somenamedtuple.**_replace**(***kwargs*)

Return a new instance of the named tuple replacing specified fields with new values:

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum],␣
↪timestamp=time.now())
```

Named tuples are also supported by generic function *copy.replace()*.

Changed in version 3.13: Raise *TypeError* instead of *ValueError* for invalid keyword arguments.

somenamedtuple.**_fields**

Tuple of strings listing the field names. Useful for introspection and for creating new named tuple types from existing named tuples.

```
>>> p._fields            # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

somenamedtuple.**_field_defaults**

Dictionary mapping field names to default values.

```
>>> Account = namedtuple('Account', ['type', 'balance'], defaults=[0])
>>> Account._field_defaults
{'balance': 0}
>>> Account('premium')
Account(type='premium', balance=0)
```

To retrieve a field whose name is stored in a string, use the *getattr()* function:

```
>>> getattr(p, 'x')
11
```

To convert a dictionary to a named tuple, use the double-star-operator (as described in tut-unpacking-arguments):

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

Since a named tuple is a regular Python class, it is easy to add or change functionality with a subclass. Here is how to add a calculated field and a fixed-width print format:

```
>>> class Point(namedtuple('Point', ['x', 'y'])):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f  y=%6.3f  hypot=%6.3f' % (self.x, self.y, self.
↪hypot)

>>> for p in Point(3, 4), Point(14, 5/7):
...     print(p)
Point: x= 3.000  y= 4.000  hypot= 5.000
Point: x=14.000  y= 0.714  hypot=14.018
```

The subclass shown above sets `__slots__` to an empty tuple. This helps keep memory requirements low by preventing the creation of instance dictionaries.

Subclassing is not useful for adding new, stored fields. Instead, simply create a new named tuple type from the *_fields* attribute:

```
>>> Point3D = namedtuple('Point3D', Point._fields + ('z',))
```

Docstrings can be customized by making direct assignments to the `__doc__` fields:

```
>>> Book = namedtuple('Book', ['id', 'title', 'authors'])
>>> Book.__doc__ += ': Hardcover book in active collection'
>>> Book.id.__doc__ = '13-digit ISBN'
>>> Book.title.__doc__ = 'Title of first printing'
>>> Book.authors.__doc__ = 'List of authors sorted by last name'
```

Changed in version 3.5: Property docstrings became writeable.

See also

- See *typing.NamedTuple* for a way to add type hints for named tuples. It also provides an elegant notation using the `class` keyword:

```
class Component(NamedTuple):
    part_number: int
    weight: float
    description: Optional[str] = None
```

- See *types.SimpleNamespace()* for a mutable namespace based on an underlying dictionary instead of a tuple.
- The *dataclasses* module provides a decorator and functions for automatically adding generated special methods to user-defined classes.

8.4.6 `OrderedDict` objects

Ordered dictionaries are just like regular dictionaries but have some extra capabilities relating to ordering operations. They have become less important now that the built-in *dict* class gained the ability to remember insertion order (this new behavior became guaranteed in Python 3.7).

Some differences from *dict* still remain:

- The regular *dict* was designed to be very good at mapping operations. Tracking insertion order was secondary.
- The *OrderedDict* was designed to be good at reordering operations. Space efficiency, iteration speed, and the performance of update operations were secondary.
- The *OrderedDict* algorithm can handle frequent reordering operations better than *dict*. As shown in the recipes below, this makes it suitable for implementing various kinds of LRU caches.
- The equality operation for *OrderedDict* checks for matching order.

  A regular *dict* can emulate the order sensitive equality test with `p == q and all(k1 == k2 for k1, k2 in zip(p, q))`.
- The *popitem()* method of *OrderedDict* has a different signature. It accepts an optional argument to specify which item is popped.

  A regular *dict* can emulate OrderedDict's `od.popitem(last=True)` with `d.popitem()` which is guaranteed to pop the rightmost (last) item.

  A regular *dict* can emulate OrderedDict's `od.popitem(last=False)` with `(k := next(iter(d)), d.pop(k))` which will return and remove the leftmost (first) item if it exists.
- *OrderedDict* has a *move_to_end()* method to efficiently reposition an element to an endpoint.

  A regular *dict* can emulate OrderedDict's `od.move_to_end(k, last=True)` with `d[k] = d.pop(k)` which will move the key and its associated value to the rightmost (last) position.

  A regular *dict* does not have an efficient equivalent for OrderedDict's `od.move_to_end(k, last=False)` which moves the key and its associated value to the leftmost (first) position.
- Until Python 3.8, *dict* lacked a `__reversed__()` method.

class collections.**OrderedDict**([*items*])

Return an instance of a *dict* subclass that has methods specialized for rearranging dictionary order.

Added in version 3.1.

popitem(*last=True*)

The *popitem()* method for ordered dictionaries returns and removes a (key, value) pair. The pairs are returned in LIFO order if *last* is true or FIFO (first-in, first-out) order if false.

move_to_end(*key*, *last=True*)

Move an existing *key* to either end of an ordered dictionary. The item is moved to the right end if *last* is true (the default) or to the beginning if *last* is false. Raises *KeyError* if the *key* does not exist:

```
>>> d = OrderedDict.fromkeys('abcde')
>>> d.move_to_end('b')
>>> ''.join(d)
'acdeb'
>>> d.move_to_end('b', last=False)
>>> ''.join(d)
'bacde'
```

Added in version 3.2.

In addition to the usual mapping methods, ordered dictionaries also support reverse iteration using *reversed()*.

Equality tests between *OrderedDict* objects are order-sensitive and are roughly equivalent to `list(od1.items())==list(od2.items())`.

Equality tests between *OrderedDict* objects and other *Mapping* objects are order-insensitive like regular dictionaries. This allows *OrderedDict* objects to be substituted anywhere a regular dictionary is used.

Changed in version 3.5: The items, keys, and values *views* of *OrderedDict* now support reverse iteration using *reversed()*.

Changed in version 3.6: With the acceptance of **PEP 468**, order is retained for keyword arguments passed to the *OrderedDict* constructor and its *update()* method.

Changed in version 3.9: Added merge (`|`) and update (`|=`) operators, specified in **PEP 584**.

`OrderedDict` Examples and Recipes

It is straightforward to create an ordered dictionary variant that remembers the order the keys were *last* inserted. If a new entry overwrites an existing entry, the original insertion position is changed and moved to the end:

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        super().__setitem__(key, value)
        self.move_to_end(key)
```

An *OrderedDict* would also be useful for implementing variants of *functools.lru_cache()*:

```
from collections import OrderedDict
from time import time

class TimeBoundedLRU:
    "LRU Cache that invalidates and refreshes old entries."

    def __init__(self, func, maxsize=128, maxage=30):
        self.cache = OrderedDict()      # { args : (timestamp, result)}
        self.func = func
        self.maxsize = maxsize
        self.maxage = maxage

    def __call__(self, *args):
        if args in self.cache:
            self.cache.move_to_end(args)
            timestamp, result = self.cache[args]
            if time() - timestamp <= self.maxage:
                return result
        result = self.func(*args)
        self.cache[args] = time(), result
```

(continues on next page)

(continued from previous page)

```
        if len(self.cache) > self.maxsize:
            self.cache.popitem(last=False)
        return result
```

```
class MultiHitLRUCache:
    """ LRU cache that defers caching a result until
        it has been requested multiple times.

        To avoid flushing the LRU cache with one-time requests,
        we don't cache until a request has been made more than once.

    """

    def __init__(self, func, maxsize=128, maxrequests=4096, cache_after=1):
        self.requests = OrderedDict()   # { uncached_key : request_count }
        self.cache = OrderedDict()      # { cached_key : function_result }
        self.func = func
        self.maxrequests = maxrequests  # max number of uncached requests
        self.maxsize = maxsize          # max number of stored return values
        self.cache_after = cache_after

    def __call__(self, *args):
        if args in self.cache:
            self.cache.move_to_end(args)
            return self.cache[args]
        result = self.func(*args)
        self.requests[args] = self.requests.get(args, 0) + 1
        if self.requests[args] <= self.cache_after:
            self.requests.move_to_end(args)
            if len(self.requests) > self.maxrequests:
                self.requests.popitem(last=False)
        else:
            self.requests.pop(args, None)
            self.cache[args] = result
            if len(self.cache) > self.maxsize:
                self.cache.popitem(last=False)
        return result
```

8.4.7 `UserDict` objects

The class, *UserDict* acts as a wrapper around dictionary objects. The need for this class has been partially supplanted by the ability to subclass directly from *dict*; however, this class can be easier to work with because the underlying dictionary is accessible as an attribute.

class collections.**UserDict**([*initialdata*])

Class that simulates a dictionary. The instance's contents are kept in a regular dictionary, which is accessible via the *data* attribute of *UserDict* instances. If *initialdata* is provided, *data* is initialized with its contents; note that a reference to *initialdata* will not be kept, allowing it to be used for other purposes.

In addition to supporting the methods and operations of mappings, *UserDict* instances provide the following attribute:

data

A real dictionary used to store the contents of the *UserDict* class.

8.4.8 `UserList` objects

This class acts as a wrapper around list objects. It is a useful base class for your own list-like classes which can inherit from them and override existing methods or add new ones. In this way, one can add new behaviors to lists.

The need for this class has been partially supplanted by the ability to subclass directly from `list`; however, this class can be easier to work with because the underlying list is accessible as an attribute.

class collections.**UserList**(*[list]*)

Class that simulates a list. The instance's contents are kept in a regular list, which is accessible via the `data` attribute of `UserList` instances. The instance's contents are initially set to a copy of *list*, defaulting to the empty list `[]`. *list* can be any iterable, for example a real Python list or a `UserList` object.

In addition to supporting the methods and operations of mutable sequences, `UserList` instances provide the following attribute:

data

A real `list` object used to store the contents of the `UserList` class.

Subclassing requirements: Subclasses of `UserList` are expected to offer a constructor which can be called with either no arguments or one argument. List operations which return a new sequence attempt to create an instance of the actual implementation class. To do so, it assumes that the constructor can be called with a single parameter, which is a sequence object used as a data source.

If a derived class does not wish to comply with this requirement, all of the special methods supported by this class will need to be overridden; please consult the sources for information about the methods which need to be provided in that case.

8.4.9 `UserString` objects

The class, `UserString` acts as a wrapper around string objects. The need for this class has been partially supplanted by the ability to subclass directly from `str`; however, this class can be easier to work with because the underlying string is accessible as an attribute.

class collections.**UserString**(*seq*)

Class that simulates a string object. The instance's content is kept in a regular string object, which is accessible via the `data` attribute of `UserString` instances. The instance's contents are initially set to a copy of *seq*. The *seq* argument can be any object which can be converted into a string using the built-in `str()` function.

In addition to supporting the methods and operations of strings, `UserString` instances provide the following attribute:

data

A real `str` object used to store the contents of the `UserString` class.

Changed in version 3.5: New methods `__getnewargs__`, `__rmod__`, `casefold`, `format_map`, `isprintable`, and `maketrans`.

8.5 `collections.abc` — Abstract Base Classes for Containers

Added in version 3.3: Formerly, this module was part of the `collections` module.

Source code: Lib/_collections_abc.py

This module provides *abstract base classes* that can be used to test whether a class provides a particular interface; for example, whether it is *hashable* or whether it is a *mapping*.

An `issubclass()` or `isinstance()` test for an interface works in one of three ways.

1) A newly written class can inherit directly from one of the abstract base classes. The class must supply the required abstract methods. The remaining mixin methods come from inheritance and can be overridden if desired. Other methods may be added as needed:

```
class C(Sequence):                          # Direct inheritance
    def __init__(self): ...                 # Extra method not required by the ABC
    def __getitem__(self, index):  ...      # Required abstract method
    def __len__(self):  ...                 # Required abstract method
    def count(self, value): ...             # Optionally override a mixin method
```

```
>>> issubclass(C, Sequence)
True
>>> isinstance(C(), Sequence)
True
```

2) Existing classes and built-in classes can be registered as "virtual subclasses" of the ABCs. Those classes should define the full API including all of the abstract methods and all of the mixin methods. This lets users rely on *issubclass()* or *isinstance()* tests to determine whether the full interface is supported. The exception to this rule is for methods that are automatically inferred from the rest of the API:

```
class D:                                    # No inheritance
    def __init__(self): ...                 # Extra method not required by the ABC
    def __getitem__(self, index):  ...      # Abstract method
    def __len__(self):  ...                 # Abstract method
    def count(self, value): ...             # Mixin method
    def index(self, value): ...             # Mixin method

Sequence.register(D)                        # Register instead of inherit
```

```
>>> issubclass(D, Sequence)
True
>>> isinstance(D(), Sequence)
True
```

In this example, class `D` does not need to define `__contains__`, `__iter__`, and `__reversed__` because the in-operator, the *iteration* logic, and the *reversed()* function automatically fall back to using `__getitem__` and `__len__`.

3) Some simple interfaces are directly recognizable by the presence of the required methods (unless those methods have been set to *None*):

```
class E:
    def __iter__(self): ...
    def __next__(self): ...
```

```
>>> issubclass(E, Iterable)
True
>>> isinstance(E(), Iterable)
True
```

Complex interfaces do not support this last technique because an interface is more than just the presence of method names. Interfaces specify semantics and relationships between methods that cannot be inferred solely from the presence of specific method names. For example, knowing that a class supplies `__getitem__`, `__len__`, and `__iter__` is insufficient for distinguishing a *Sequence* from a *Mapping*.

Added in version 3.9: These abstract classes now support `[]`. See *Generic Alias Type* and **PEP 585**.

8.5.1 Collections Abstract Base Classes

The collections module offers the following *ABCs*:

ABC	Inherits from	Abstract Methods	Mixin Methods
Container[1]		`__contains__`	
Hashable[Page 277, 1]		`__hash__`	
Iterable[Page 277, 12]		`__iter__`	
Iterator[Page 277, 1]	*Iterable*	`__next__`	`__iter__`
Reversible[Page 277, 1]	*Iterable*	`__reversed__`	
Generator[Page 277, 1]	*Iterator*	`send`, `throw`	`close`, `__iter__`, `__next__`
Sized[Page 277, 1]		`__len__`	
Callable[Page 277, 1]		`__call__`	
Collection[Page 277, 1]	*Sized*, *Iterable*, *Container*	`__contains__`, `__iter__`, `__len__`	
Sequence	*Reversible*, *Collection*	`__getitem__`, `__len__`	`__contains__`, `__iter__`, `__reversed__`, `index`, and `count`
MutableSequence	*Sequence*	`__getitem__`, `__setitem__`, `__delitem__`, `__len__`, `insert`	Inherited *Sequence* methods and `append`, `clear`, `reverse`, `extend`, `pop`, `remove`, and `__iadd__`
ByteString	*Sequence*	`__getitem__`, `__len__`	Inherited *Sequence* methods
Set	*Collection*	`__contains__`, `__iter__`, `__len__`	`__le__`, `__lt__`, `__eq__`, `__ne__`, `__gt__`, `__ge__`, `__and__`, `__or__`, `__sub__`, `__rsub__`, `__xor__`, `__rxor__` and `isdisjoint`
MutableSet	*Set*	`__contains__`, `__iter__`, `__len__`, `add`, `discard`	Inherited *Set* methods and `clear`, `pop`, `remove`, `__ior__`, `__iand__`, `__ixor__`, and `__isub__`
Mapping	*Collection*	`__getitem__`, `__iter__`, `__len__`	`__contains__`, `keys`, `items`, `values`, `get`, `__eq__`, and `__ne__`
MutableMapping	*Mapping*	`__getitem__`, `__setitem__`, `__delitem__`, `__iter__`, `__len__`	Inherited *Mapping* methods and `pop`, `popitem`, `clear`, `update`, and `setdefault`
MappingView	*Sized*		`__init__`, `__len__` and `__repr__`
ItemsView	*MappingView*, *Set*		`__contains__`, `__iter__`
KeysView	*MappingView*, *Set*		`__contains__`, `__iter__`
ValuesView	*MappingView*, *Collection*		`__contains__`, `__iter__`
Awaitable[Page 277, 1]		`__await__`	
Coroutine[Page 277, 1]	*Awaitable*	`send`, `throw`	`close`
AsyncIterable[Page 277, 1]		`__aiter__`	
AsyncIterator[Page 277, 1]	*AsyncIterable*	`__anext__`	`__aiter__`
AsyncGenerator[Page 277, 1]	*AsyncIterator*	`asend`, `athrow`	`aclose`, `__aiter__`, `__anext__`

8.5.2 Collections Abstract Base Classes – Detailed Descriptions

class collections.abc.**Container**

ABC for classes that provide the __contains__() method.

class collections.abc.**Hashable**

ABC for classes that provide the __hash__() method.

class collections.abc.**Sized**

ABC for classes that provide the __len__() method.

class collections.abc.**Callable**

ABC for classes that provide the __call__() method.

See *Annotating callable objects* for details on how to use `Callable` in type annotations.

class collections.abc.**Iterable**

ABC for classes that provide the *__iter__()* method.

Checking `isinstance(obj, Iterable)` detects classes that are registered as *Iterable* or that have an *__iter__()* method, but it does not detect classes that iterate with the __getitem__() method. The only reliable way to determine whether an object is *iterable* is to call `iter(obj)`.

class collections.abc.**Collection**

ABC for sized iterable container classes.

Added in version 3.6.

class collections.abc.**Iterator**

ABC for classes that provide the *__iter__()* and *__next__()* methods. See also the definition of *iterator*.

class collections.abc.**Reversible**

ABC for iterable classes that also provide the __reversed__() method.

Added in version 3.6.

class collections.abc.**Generator**

ABC for *generator* classes that implement the protocol defined in **PEP 342** that extends *iterators* with the `send()`, `throw()` and `close()` methods.

See *Annotating generators and coroutines* for details on using `Generator` in type annotations.

Added in version 3.5.

class collections.abc.**Sequence**

class collections.abc.**MutableSequence**

class collections.abc.**ByteString**

ABCs for read-only and mutable *sequences*.

Implementation note: Some of the mixin methods, such as *__iter__()*, __reversed__() and `index()`, make repeated calls to the underlying __getitem__() method. Consequently, if __getitem__() is implemented with constant access speed, the mixin methods will have linear performance; however, if the underlying method is linear (as it would be with a linked list), the mixins will have quadratic performance and will likely need to be overridden.

Changed in version 3.5: The index() method added support for *stop* and *start* arguments.

Deprecated since version 3.12, will be removed in version 3.14: The *ByteString* ABC has been deprecated. For use in typing, prefer a union, like `bytes | bytearray`, or *collections.abc.Buffer*. For use as an ABC, prefer *Sequence* or *collections.abc.Buffer*.

[1] These ABCs override *__subclasshook__()* to support testing an interface by verifying the required methods are present and have not been set to *None*. This only works for simple interfaces. More complex interfaces require registration or direct subclassing.

[2] Checking `isinstance(obj, Iterable)` detects classes that are registered as *Iterable* or that have an *__iter__()* method, but it does not detect classes that iterate with the __getitem__() method. The only reliable way to determine whether an object is *iterable* is to call `iter(obj)`.

class collections.abc.**Set**

class collections.abc.**MutableSet**

ABCs for read-only and mutable *sets*.

class collections.abc.**Mapping**

class collections.abc.**MutableMapping**

ABCs for read-only and mutable *mappings*.

class collections.abc.**MappingView**

class collections.abc.**ItemsView**

class collections.abc.**KeysView**

class collections.abc.**ValuesView**

ABCs for mapping, items, keys, and values *views*.

class collections.abc.**Awaitable**

ABC for *awaitable* objects, which can be used in `await` expressions. Custom implementations must provide the `__await__()` method.

Coroutine objects and instances of the `Coroutine` ABC are all instances of this ABC.

> **Note**
>
> In CPython, generator-based coroutines (*generators* decorated with `@types.coroutine`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Awaitable)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

Added in version 3.5.

class collections.abc.**Coroutine**

ABC for *coroutine* compatible classes. These implement the following methods, defined in coroutine-objects: `send()`, `throw()`, and `close()`. Custom implementations must also implement `__await__()`. All `Coroutine` instances are also instances of `Awaitable`.

> **Note**
>
> In CPython, generator-based coroutines (*generators* decorated with `@types.coroutine`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Coroutine)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

See *Annotating generators and coroutines* for details on using `Coroutine` in type annotations. The variance and order of type parameters correspond to those of `Generator`.

Added in version 3.5.

class collections.abc.**AsyncIterable**

ABC for classes that provide an `__aiter__` method. See also the definition of *asynchronous iterable*.

Added in version 3.5.

class collections.abc.**AsyncIterator**

ABC for classes that provide `__aiter__` and `__anext__` methods. See also the definition of *asynchronous iterator*.

Added in version 3.5.

class collections.abc.**AsyncGenerator**

ABC for *asynchronous generator* classes that implement the protocol defined in **PEP 525** and **PEP 492**.

See *Annotating generators and coroutines* for details on using `AsyncGenerator` in type annotations.

Added in version 3.6.

class collections.abc.**Buffer**

ABC for classes that provide the `__buffer__()` method, implementing the buffer protocol. See **PEP 688**.

Added in version 3.12.

8.5.3 Examples and Recipes

ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```
size = None
if isinstance(myvar, collections.abc.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full *Set* API, it is only necessary to supply the three underlying abstract methods: `__contains__()`, *__iter__()*, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and *isdisjoint()*:

```
class ListBasedSet(collections.abc.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2            # The __and__() method is supported automatically
```

Notes on using *Set* and *MutableSet* as a mixin:

(1) Since some set operations create new sets, the default mixin methods need a way to create new instances from an *iterable*. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal *classmethod* called `_from_iterable()` which calls `cls(iterable)` to produce a new set. If the *Set* mixin is being used in a class with a different constructor signature, you will need to override `_from_iterable()` with a classmethod or regular method that can construct new instances from an iterable argument.

(2) To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.

(3) The *Set* mixin provides a `_hash()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are *hashable* or immutable. To add set hashability using mixins, inherit from both *Set()* and *Hashable()*, then define `__hash__ = Set._hash`.

- OrderedSet recipe for an example built on `MutableSet`.
- For more about ABCs, see the `abc` module and **PEP 3119**.

8.6 `heapq` — Heap queue algorithm

Source code: Lib/heapq.py

This module provides an implementation of the heap queue algorithm, also known as the priority queue algorithm.

Heaps are binary trees for which every parent node has a value less than or equal to any of its children. We refer to this condition as the heap invariant.

This implementation uses arrays for which `heap[k] <= heap[2*k+1]` and `heap[k] <= heap[2*k+2]` for all *k*, counting elements from zero. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that its smallest element is always the root, `heap[0]`.

The API below differs from textbook heap algorithms in two aspects: (a) We use zero-based indexing. This makes the relationship between the index for a node and the indexes for its children slightly less obvious, but is more suitable since Python uses zero-based indexing. (b) Our pop method returns the smallest item, not the largest (called a "min heap" in textbooks; a "max heap" is more common in texts because of its suitability for in-place sorting).

These two make it possible to view the heap as a regular Python list without surprises: `heap[0]` is the smallest item, and `heap.sort()` maintains the heap invariant!

To create a heap, use a list initialized to `[]`, or you can transform a populated list into a heap via function `heapify()`.

The following functions are provided:

`heapq.`**`heappush`**(*heap*, *item*)

Push the value *item* onto the *heap*, maintaining the heap invariant.

`heapq.`**`heappop`**(*heap*)

Pop and return the smallest item from the *heap*, maintaining the heap invariant. If the heap is empty, `IndexError` is raised. To access the smallest item without popping it, use `heap[0]`.

`heapq.`**`heappushpop`**(*heap*, *item*)

Push *item* on the heap, then pop and return the smallest item from the *heap*. The combined action runs more efficiently than `heappush()` followed by a separate call to `heappop()`.

`heapq.`**`heapify`**(*x*)

Transform list *x* into a heap, in-place, in linear time.

`heapq.`**`heapreplace`**(*heap*, *item*)

Pop and return the smallest item from the *heap*, and also push the new *item*. The heap size doesn't change. If the heap is empty, `IndexError` is raised.

This one step operation is more efficient than a `heappop()` followed by `heappush()` and can be more appropriate when using a fixed-size heap. The pop/push combination always returns an element from the heap and replaces it with *item*.

The value returned may be larger than the *item* added. If that isn't desired, consider using `heappushpop()` instead. Its push/pop combination returns the smaller of the two values, leaving the larger value on the heap.

The module also offers three general purpose functions based on heaps.

`heapq.`**`merge`**(**iterables*, *key=None*, *reverse=False*)

Merge multiple sorted inputs into a single sorted output (for example, merge timestamped entries from multiple log files). Returns an *iterator* over the sorted values.

Similar to `sorted(itertools.chain(*iterables))` but returns an iterable, does not pull the data into memory all at once, and assumes that each of the input streams is already sorted (smallest to largest).

Has two optional arguments which must be specified as keyword arguments.

key specifies a *key function* of one argument that is used to extract a comparison key from each input element. The default value is `None` (compare the elements directly).

reverse is a boolean value. If set to `True`, then the input elements are merged as if each comparison were reversed. To achieve behavior similar to `sorted(itertools.chain(*iterables), reverse=True)`, all iterables must be sorted from largest to smallest.

Changed in version 3.5: Added the optional *key* and *reverse* parameters.

`heapq.`**`nlargest`**(*n*, *iterable*, *key=None*)

Return a list with the *n* largest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key, reverse=True)[:n]`.

`heapq.`**`nsmallest`**(*n*, *iterable*, *key=None*)

Return a list with the *n* smallest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key)[:n]`.

The latter two functions perform best for smaller values of *n*. For larger values, it is more efficient to use the *sorted()* function. Also, when `n==1`, it is more efficient to use the built-in *min()* and *max()* functions. If repeated usage of these functions is required, consider turning the iterable into an actual heap.

8.6.1 Basic Examples

A heapsort can be implemented by pushing all values onto a heap and then popping off the smallest values one at a time:

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

This is similar to `sorted(iterable)`, but unlike *sorted()*, this implementation is not stable.

Heap elements can be tuples. This is useful for assigning comparison values (such as task priorities) alongside the main record being tracked:

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

8.6.2 Priority Queue Implementation Notes

A priority queue is common use for a heap, and it presents several implementation challenges:

- Sort stability: how do you get two tasks with equal priorities to be returned in the order they were originally added?
- Tuple comparison breaks for (priority, task) pairs if the priorities are equal and the tasks do not have a default comparison order.
- If the priority of a task changes, how do you move it to a new position in the heap?

- Or if a pending task needs to be deleted, how do you find it and remove it from the queue?

A solution to the first two challenges is to store entries as 3-element list including the priority, an entry count, and the task. The entry count serves as a tie-breaker so that two tasks with the same priority are returned in the order they were added. And since no two entry counts are the same, the tuple comparison will never attempt to directly compare two tasks.

Another solution to the problem of non-comparable tasks is to create a wrapper class that ignores the task item and only compares the priority field:

```
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

The remaining challenges revolve around finding a pending task and making changes to its priority or removing it entirely. Finding a task can be done with a dictionary pointing to an entry in the queue.

Removing the entry or changing its priority is more difficult because it would break the heap structure invariants. So, a possible solution is to mark the entry as removed and add a new entry with the revised priority:

```
pq = []                         # list of entries arranged in a heap
entry_finder = {}               # mapping of tasks to entries
REMOVED = '<removed-task>'      # placeholder for a removed task
counter = itertools.count()     # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED.  Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
    'Remove and return the lowest priority task. Raise KeyError if empty.'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
            del entry_finder[task]
            return task
    raise KeyError('pop from an empty priority queue')
```

8.6.3 Theory

Heaps are arrays for which `a[k] <= a[2*k+1]` and `a[k] <= a[2*k+2]` for all *k*, counting elements from 0. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that `a[0]` is always its smallest element.

The strange invariant above is meant to be an efficient memory representation for a tournament. The numbers below are *k*, not `a[k]`:

```
                               0

              1                                2

      3               4                5               6

  7       8       9       10      11      12      13      14

15 16   17 18   19 20   21 22   23 24   25 26   27 28   29 30
```

In the tree above, each cell *k* is topping `2*k+1` and `2*k+2`. In a usual binary tournament we see in sports, each cell is the winner over the two cells it tops, and we can trace the winner down the tree to see all opponents s/he had. However, in many computer applications of such tournaments, we do not need to trace the history of a winner. To be more memory efficient, when a winner is promoted, we try to replace it by something else at a lower level, and the rule becomes that a cell and the two cells it tops contain three different items, but the top cell "wins" over the two topped cells.

If this heap invariant is protected at all time, index 0 is clearly the overall winner. The simplest algorithmic way to remove it and find the "next" winner is to move some loser (let's say cell 30 in the diagram above) into the 0 position, and then percolate this new 0 down the tree, exchanging values, until the invariant is re-established. This is clearly logarithmic on the total number of items in the tree. By iterating over all items, you get an $O(n \log n)$ sort.

A nice feature of this sort is that you can efficiently insert new items while the sort is going on, provided that the inserted items are not "better" than the last 0'th element you extracted. This is especially useful in simulation contexts, where the tree holds all incoming events, and the "win" condition means the smallest scheduled time. When an event schedules other events for execution, they are scheduled into the future, so they can easily go into the heap. So, a heap is a good structure for implementing schedulers (this is what I used for my MIDI sequencer :-).

Various structures for implementing schedulers have been extensively studied, and heaps are good for this, as they are reasonably speedy, the speed is almost constant, and the worst case is not much different than the average case. However, there are other representations which are more efficient overall, yet the worst cases might be terrible.

Heaps are also very useful in big disk sorts. You most probably all know that a big sort implies producing "runs" (which are pre-sorted sequences, whose size is usually related to the amount of CPU memory), followed by a merging passes for these runs, which merging is often very cleverly organised[1]. It is very important that the initial sort produces the longest runs possible. Tournaments are a good way to achieve that. If, using all the memory available to hold a tournament, you replace and percolate items that happen to fit the current run, you'll produce runs which are twice the size of the memory for random input, and much better for input fuzzily ordered.

Moreover, if you output the 0'th item on disk and get an input which may not fit in the current tournament (because the value "wins" over the last output value), it cannot fit in the heap, so the size of the heap decreases. The freed memory could be cleverly reused immediately for progressively building a second heap, which grows at exactly the same rate the first heap is melting. When the first heap completely vanishes, you switch heaps and start a new run. Clever and quite effective!

In a word, heaps are useful memory structures to know. I use them in a few applications, and I think it is good to keep a 'heap' module around. :-)

8.7 `bisect` — Array bisection algorithm

Source code: Lib/bisect.py

This module provides support for maintaining a list in sorted order without having to sort the list after each insertion. For long lists of items with expensive comparison operations, this can be an improvement over linear searches or frequent resorting.

[1] The disk balancing algorithms which are current, nowadays, are more annoying than clever, and this is a consequence of the seeking capabilities of the disks. On devices which cannot seek, like big tape drives, the story was quite different, and one had to be very clever to ensure (far in advance) that each tape movement will be the most effective possible (that is, will best participate at "progressing" the merge). Some tapes were even able to read backwards, and this was also used to avoid the rewinding time. Believe me, real good tape sorts were quite spectacular to watch! From all times, sorting has always been a Great Art! :-)

The module is called *bisect* because it uses a basic bisection algorithm to do its work. Unlike other bisection tools that search for a specific value, the functions in this module are designed to locate an insertion point. Accordingly, the functions never call an `__eq__()` method to determine whether a value has been found. Instead, the functions only call the `__lt__()` method and will return an insertion point between values in an array.

The following functions are provided:

`bisect.`**`bisect_left`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

Locate the insertion point for *x* in *a* to maintain sorted order. The parameters *lo* and *hi* may be used to specify a subset of the list which should be considered; by default the entire list is used. If *x* is already present in *a*, the insertion point will be before (to the left of) any existing entries. The return value is suitable for use as the first parameter to `list.insert()` assuming that *a* is already sorted.

The returned insertion point *ip* partitions the array *a* into two slices such that `all(elem < x for elem in a[lo : ip])` is true for the left slice and `all(elem >= x for elem in a[ip : hi])` is true for the right slice.

key specifies a *key function* of one argument that is used to extract a comparison key from each element in the array. To support searching complex records, the key function is not applied to the *x* value.

If *key* is `None`, the elements are compared directly and no key function is called.

Changed in version 3.10: Added the *key* parameter.

`bisect.`**`bisect_right`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

`bisect.`**`bisect`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

Similar to *bisect_left()*, but returns an insertion point which comes after (to the right of) any existing entries of *x* in *a*.

The returned insertion point *ip* partitions the array *a* into two slices such that `all(elem <= x for elem in a[lo : ip])` is true for the left slice and `all(elem > x for elem in a[ip : hi])` is true for the right slice.

Changed in version 3.10: Added the *key* parameter.

`bisect.`**`insort_left`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

Insert *x* in *a* in sorted order.

This function first runs *bisect_left()* to locate an insertion point. Next, it runs the `insert()` method on *a* to insert *x* at the appropriate position to maintain sort order.

To support inserting records in a table, the *key* function (if any) is applied to *x* for the search step but not for the insertion step.

Keep in mind that the *O*(log *n*) search is dominated by the slow *O*(*n*) insertion step.

Changed in version 3.10: Added the *key* parameter.

`bisect.`**`insort_right`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

`bisect.`**`insort`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

Similar to *insort_left()*, but inserting *x* in *a* after any existing entries of *x*.

This function first runs *bisect_right()* to locate an insertion point. Next, it runs the `insert()` method on *a* to insert *x* at the appropriate position to maintain sort order.

To support inserting records in a table, the *key* function (if any) is applied to *x* for the search step but not for the insertion step.

Keep in mind that the *O*(log *n*) search is dominated by the slow *O*(*n*) insertion step.

Changed in version 3.10: Added the *key* parameter.

8.7.1 Performance Notes

When writing time sensitive code using *bisect()* and *insort()*, keep these thoughts in mind:

- Bisection is effective for searching ranges of values. For locating specific values, dictionaries are more performant.
- The *insort()* functions are $O(n)$ because the logarithmic search step is dominated by the linear time insertion step.
- The search functions are stateless and discard key function results after they are used. Consequently, if the search functions are used in a loop, the key function may be called again and again on the same array elements. If the key function isn't fast, consider wrapping it with `functools.cache()` to avoid duplicate computations. Alternatively, consider searching an array of precomputed keys to locate the insertion point (as shown in the examples section below).

See also

- Sorted Collections is a high performance module that uses *bisect* to managed sorted collections of data.
- The SortedCollection recipe uses bisect to build a full-featured collection class with straight-forward search methods and support for a key-function. The keys are precomputed to save unnecessary calls to the key function during searches.

8.7.2 Searching Sorted Lists

The above *bisect functions* are useful for finding insertion points but can be tricky or awkward to use for common searching tasks. The following five functions show how to transform them into the standard lookups for sorted lists:

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
```

(continues on next page)

(continued from previous page)

```
    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError
```

8.7.3 Examples

The *bisect()* function can be useful for numeric table lookups. This example uses *bisect()* to look up a letter grade for an exam score (say) based on a set of ordered numeric breakpoints: 90 and up is an 'A', 80 to 89 is a 'B', and so on:

```
>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
...     i = bisect(breakpoints, score)
...     return grades[i]
...
>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']
```

The *bisect()* and *insort()* functions also work with lists of tuples. The *key* argument can serve to extract the field used for ordering records in a table:

```
>>> from collections import namedtuple
>>> from operator import attrgetter
>>> from bisect import bisect, insort
>>> from pprint import pprint

>>> Movie = namedtuple('Movie', ('name', 'released', 'director'))

>>> movies = [
...     Movie('Jaws', 1975, 'Spielberg'),
...     Movie('Titanic', 1997, 'Cameron'),
...     Movie('The Birds', 1963, 'Hitchcock'),
...     Movie('Aliens', 1986, 'Cameron')
... ]

>>> # Find the first movie released after 1960
>>> by_year = attrgetter('released')
>>> movies.sort(key=by_year)
>>> movies[bisect(movies, 1960, key=by_year)]
Movie(name='The Birds', released=1963, director='Hitchcock')

>>> # Insert a movie while maintaining sort order
>>> romance = Movie('Love Story', 1970, 'Hiller')
>>> insort(movies, romance, key=by_year)
>>> pprint(movies)
[Movie(name='The Birds', released=1963, director='Hitchcock'),
 Movie(name='Love Story', released=1970, director='Hiller'),
 Movie(name='Jaws', released=1975, director='Spielberg'),
 Movie(name='Aliens', released=1986, director='Cameron'),
 Movie(name='Titanic', released=1997, director='Cameron')]
```

If the key function is expensive, it is possible to avoid repeated function calls by searching a list of precomputed keys to find the index of a record:

```
>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])       # Or use operator.itemgetter(1).
```

(continues on next page)

(continued from previous page)

```
>>> keys = [r[1] for r in data]         # Precompute a list of keys.
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)
```

8.8 `array` — Efficient arrays of numeric values

This module defines an object type which can compactly represent an array of basic values: characters, integers, floating-point numbers. Arrays are sequence types and behave very much like lists, except that the type of objects stored in them is constrained. The type is specified at object creation time by using a *type code*, which is a single character. The following type codes are defined:

Type code	C Type	Python Type	Minimum size in bytes	Notes
`'b'`	signed char	int	1	
`'B'`	unsigned char	int	1	
`'u'`	wchar_t	Unicode character	2	(1)
`'w'`	Py_UCS4	Unicode character	4	
`'h'`	signed short	int	2	
`'H'`	unsigned short	int	2	
`'i'`	signed int	int	2	
`'I'`	unsigned int	int	2	
`'l'`	signed long	int	4	
`'L'`	unsigned long	int	4	
`'q'`	signed long long	int	8	
`'Q'`	unsigned long long	int	8	
`'f'`	float	float	4	
`'d'`	double	float	8	

Notes:

(1) It can be 16 bits or 32 bits depending on the platform.

Changed in version 3.9: `array('u')` now uses `wchar_t` as C type instead of deprecated `Py_UNICODE`. This change doesn't affect its behavior because `Py_UNICODE` is alias of `wchar_t` since Python 3.3.

Deprecated since version 3.3, will be removed in version 3.16: Please migrate to `'w'` typecode.

The actual representation of values is determined by the machine architecture (strictly speaking, by the C implementation). The actual size can be accessed through the *array.itemsize* attribute.

The module defines the following item:

`array.`**`typecodes`**

A string with all available type codes.

The module defines the following type:

`class` `array.`**`array`**(*typecode*[, *initializer*])

A new array whose items are restricted by *typecode*, and initialized from the optional *initializer* value, which must be a *bytes* or *bytearray* object, a Unicode string, or iterable over elements of the appropriate type.

If given a *bytes* or *bytearray* object, the initializer is passed to the new array's *frombytes()* method; if given a Unicode string, the initializer is passed to the *fromunicode()* method; otherwise, the initializer's iterator is passed to the *extend()* method to add initial items to the array.

Array objects support the ordinary sequence operations of indexing, slicing, concatenation, and multiplication. When using slice assignment, the assigned value must be an array object with the same type code; in all other cases, *TypeError* is raised. Array objects also implement the buffer interface, and may be used wherever *bytes-like objects* are supported.

Raises an *auditing event* `array.__new__` with arguments `typecode`, `initializer`.

typecode

The typecode character used to create the array.

itemsize

The length in bytes of one array item in the internal representation.

append(*x*)

Append a new item with value *x* to the end of the array.

buffer_info()

Return a tuple `(address, length)` giving the current memory address and the length in elements of the buffer used to hold array's contents. The size of the memory buffer in bytes can be computed as `array.buffer_info()[1] * array.itemsize`. This is occasionally useful when working with low-level (and inherently unsafe) I/O interfaces that require memory addresses, such as certain `ioctl()` operations. The returned numbers are valid as long as the array exists and no length-changing operations are applied to it.

> **Note**
>
> When using array objects from code written in C or C++ (the only way to effectively make use of this information), it makes more sense to use the buffer interface supported by array objects. This method is maintained for backward compatibility and should be avoided in new code. The buffer interface is documented in bufferobjects.

byteswap()

"Byteswap" all items of the array. This is only supported for values which are 1, 2, 4, or 8 bytes in size; for other types of values, *RuntimeError* is raised. It is useful when reading data from a file written on a machine with a different byte order.

count(*x*)

Return the number of occurrences of *x* in the array.

extend(*iterable*)

Append items from *iterable* to the end of the array. If *iterable* is another array, it must have *exactly* the same type code; if not, *TypeError* will be raised. If *iterable* is not an array, it must be iterable and its elements must be the right type to be appended to the array.

frombytes(*buffer*)

Appends items from the *bytes-like object*, interpreting its content as an array of machine values (as if it had been read from a file using the *fromfile()* method).

Added in version 3.2: `fromstring()` is renamed to *frombytes()* for clarity.

fromfile(*f*, *n*)

Read *n* items (as machine values) from the *file object* *f* and append them to the end of the array. If less than *n* items are available, *EOFError* is raised, but the items that were available are still inserted into the array.

fromlist(*list*)

Append items from the list. This is equivalent to `for x in list: a.append(x)` except that if there is a type error, the array is unchanged.

fromunicode(*s*)

Extends this array with data from the given Unicode string. The array must have type code `'u'` or `'w'`; otherwise a *ValueError* is raised. Use `array.frombytes(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

index(*x*[, *start*[, *stop*]])

Return the smallest *i* such that *i* is the index of the first occurrence of *x* in the array. The optional arguments *start* and *stop* can be specified to search for *x* within a subsection of the array. Raise *ValueError* if *x* is not found.

Changed in version 3.10: Added optional *start* and *stop* parameters.

insert(*i*, *x*)

Insert a new item with value *x* in the array before position *i*. Negative values are treated as being relative to the end of the array.

pop([*i*])

Removes the item with the index *i* from the array and returns it. The optional argument defaults to `-1`, so that by default the last item is removed and returned.

remove(*x*)

Remove the first occurrence of *x* from the array.

clear()

Remove all elements from the array.

Added in version 3.13.

reverse()

Reverse the order of the items in the array.

tobytes()

Convert the array to an array of machine values and return the bytes representation (the same sequence of bytes that would be written to a file by the *tofile()* method.)

Added in version 3.2: `tostring()` is renamed to *tobytes()* for clarity.

tofile(*f*)

Write all items (as machine values) to the *file object* *f*.

tolist()

Convert the array to an ordinary list with the same items.

tounicode()

Convert the array to a Unicode string. The array must have a type `'u'` or `'w'`; otherwise a *ValueError* is raised. Use `array.tobytes().decode(enc)` to obtain a Unicode string from an array of some other type.

The string representation of array objects has the form `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a Unicode string if the *typecode* is `'u'` or `'w'`, otherwise it is a list of numbers. The string representation is guaranteed to be able to be converted back to an array with the same type and value using *eval()*, so long as the *array* class has been imported using `from array import array`. Variables `inf` and `nan` must also be defined if it contains corresponding floating-point values. Examples:

```
array('l')
array('w', 'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14, -inf, nan])
```

8.9 `weakref` — Weak references

Source code: Lib/weakref.py

The *weakref* module allows the Python programmer to create *weak references* to objects.

In the following, the term *referent* means the object which is referred to by a weak reference.

A weak reference to an object is not enough to keep the object alive: when the only remaining references to a referent are weak references, *garbage collection* is free to destroy the referent and reuse its memory for something else. However, until the object is actually destroyed the weak reference may return the object even if there are no strong references to it.

A primary use for weak references is to implement caches or mappings holding large objects, where it's desired that a large object not be kept alive solely because it appears in a cache or mapping.

For example, if you have a number of large binary image objects, you may wish to associate a name with each. If you used a Python dictionary to map names to images, or images to names, the image objects would remain alive just because they appeared as values or keys in the dictionaries. The *WeakKeyDictionary* and *WeakValueDictionary* classes supplied by the *weakref* module are an alternative, using weak references to construct mappings that don't keep objects alive solely because they appear in the mapping objects. If, for example, an image object is a value in a *WeakValueDictionary*, then when the last remaining references to that image object are the weak references held by weak mappings, garbage collection can reclaim the object, and its corresponding entries in weak mappings are simply deleted.

WeakKeyDictionary and *WeakValueDictionary* use weak references in their implementation, setting up callback functions on the weak references that notify the weak dictionaries when a key or value has been reclaimed by garbage collection. *WeakSet* implements the *set* interface, but keeps weak references to its elements, just like a *WeakKeyDictionary* does.

finalize provides a straight forward way to register a cleanup function to be called when an object is garbage collected. This is simpler to use than setting up a callback function on a raw weak reference, since the module automatically ensures that the finalizer remains alive until the object is collected.

Most programs should find that using one of these weak container types or *finalize* is all they need – it's not usually necessary to create your own weak references directly. The low-level machinery is exposed by the *weakref* module for the benefit of advanced uses.

Not all objects can be weakly referenced. Objects which support weak references include class instances, functions written in Python (but not in C), instance methods, sets, frozensets, some *file objects*, *generators*, type objects, sockets, arrays, deques, regular expression pattern objects, and code objects.

Changed in version 3.2: Added support for thread.lock, threading.Lock, and code objects.

Several built-in types such as *list* and *dict* do not directly support weak references but can add support through subclassing:

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)   # this object is weak referenceable
```

CPython implementation detail: Other built-in types such as *tuple* and *int* do not support weak references even when subclassed.

Extension types can easily be made to support weak references; see weakref-support.

When __slots__ are defined for a given type, weak reference support is disabled unless a '__weakref__' string is also present in the sequence of strings in the __slots__ declaration. See __slots__ documentation for details.

class weakref.**ref**(*object*[, *callback*])

Return a weak reference to *object*. The original object can be retrieved by calling the reference object if the referent is still alive; if the referent is no longer alive, calling the reference object will cause *None* to be returned. If *callback* is provided and not *None*, and the returned weakref object is still alive, the callback will be called when the object is about to be finalized; the weak reference object will be passed as the only parameter to the callback; the referent will no longer be available.

It is allowable for many weak references to be constructed for the same object. Callbacks registered for each weak reference will be called from the most recently registered callback to the oldest registered callback.

Exceptions raised by the callback will be noted on the standard error output, but cannot be propagated; they are handled in exactly the same way as exceptions raised from an object's __del__() method.

Weak references are *hashable* if the *object* is hashable. They will maintain their hash value even after the *object* was deleted. If *hash()* is called the first time only after the *object* was deleted, the call will raise *TypeError*.

Weak references support tests for equality, but not ordering. If the referents are still alive, two references have the same equality relationship as their referents (regardless of the *callback*). If either referent has been deleted, the references are equal only if the reference objects are the same object.

This is a subclassable type rather than a factory function.

__callback__

This read-only attribute returns the callback currently associated to the weakref. If there is no callback or if the referent of the weakref is no longer alive then this attribute will have value None.

Changed in version 3.4: Added the *__callback__* attribute.

weakref.**proxy**(*object*[, *callback*])

Return a proxy to *object* which uses a weak reference. This supports use of the proxy in most contexts instead of requiring the explicit dereferencing used with weak reference objects. The returned object will have a type of either ProxyType or CallableProxyType, depending on whether *object* is callable. Proxy objects are not *hashable* regardless of the referent; this avoids a number of problems related to their fundamentally mutable nature, and prevents their use as dictionary keys. *callback* is the same as the parameter of the same name to the *ref()* function.

Accessing an attribute of the proxy object after the referent is garbage collected raises *ReferenceError*.

Changed in version 3.8: Extended the operator support on proxy objects to include the matrix multiplication operators @ and @=.

weakref.**getweakrefcount**(*object*)

Return the number of weak references and proxies which refer to *object*.

weakref.**getweakrefs**(*object*)

Return a list of all weak reference and proxy objects which refer to *object*.

class weakref.**WeakKeyDictionary**([*dict*])

Mapping class that references keys weakly. Entries in the dictionary will be discarded when there is no longer a strong reference to the key. This can be used to associate additional data with an object owned by other parts of an application without adding attributes to those objects. This can be especially useful with objects that override attribute accesses.

Note that when a key with equal value to an existing key (but not equal identity) is inserted into the dictionary, it replaces the value but does not replace the existing key. Due to this, when the reference to the original key is deleted, it also deletes the entry in the dictionary:

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1   # d = {k1: 1}
>>> d[k2] = 2   # d = {k1: 2}
>>> del k1      # d = {}
```

A workaround would be to remove the key prior to reassignment:

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1   # d = {k1: 1}
>>> del d[k1]
>>> d[k2] = 2   # d = {k2: 2}
>>> del k1      # d = {k2: 2}
```

Changed in version 3.9: Added support for `|` and `|=` operators, as specified in **PEP 584**.

WeakKeyDictionary objects have an additional method that exposes the internal references directly. The references are not guaranteed to be "live" at the time they are used, so the result of calling the references needs to be checked before being used. This can be used to avoid creating references that will cause the garbage collector to keep the keys around longer than needed.

WeakKeyDictionary.**keyrefs**()

Return an iterable of the weak references to the keys.

class weakref.**WeakValueDictionary**([*dict*])

Mapping class that references values weakly. Entries in the dictionary will be discarded when no strong reference to the value exists any more.

Changed in version 3.9: Added support for `|` and `|=` operators, as specified in **PEP 584**.

WeakValueDictionary objects have an additional method that has the same issues as the *WeakKeyDictionary.keyrefs()* method.

WeakValueDictionary.**valuerefs**()

Return an iterable of the weak references to the values.

class weakref.**WeakSet**([*elements*])

Set class that keeps weak references to its elements. An element will be discarded when no strong reference to it exists any more.

class weakref.**WeakMethod**(*method*[, *callback*])

A custom *ref* subclass which simulates a weak reference to a bound method (i.e., a method defined on a class and looked up on an instance). Since a bound method is ephemeral, a standard weak reference cannot keep hold of it. *WeakMethod* has special code to recreate the bound method until either the object or the original function dies:

```
>>> class C:
...     def method(self):
...         print("method called!")
...
>>> c = C()
>>> r = weakref.ref(c.method)
>>> r()
>>> r = weakref.WeakMethod(c.method)
>>> r()
```

(continues on next page)

(continued from previous page)

```
<bound method C.method of <__main__.C object at 0x7fc859830220>>
>>> r()()
method called!
>>> del c
>>> gc.collect()
0
>>> r()
>>>
```

callback is the same as the parameter of the same name to the `ref()` function.

Added in version 3.4.

class weakref.**finalize**(*obj*, *func*, */*, **args*, ***kwargs*)

Return a callable finalizer object which will be called when *obj* is garbage collected. Unlike an ordinary weak reference, a finalizer will always survive until the reference object is collected, greatly simplifying lifecycle management.

A finalizer is considered *alive* until it is called (either explicitly or at garbage collection), and after that it is *dead*. Calling a live finalizer returns the result of evaluating `func(*arg, **kwargs)`, whereas calling a dead finalizer returns `None`.

Exceptions raised by finalizer callbacks during garbage collection will be shown on the standard error output, but cannot be propagated. They are handled in the same way as exceptions raised from an object's `__del__()` method or a weak reference's callback.

When the program exits, each remaining live finalizer is called unless its `atexit` attribute has been set to false. They are called in reverse order of creation.

A finalizer will never invoke its callback during the later part of the *interpreter shutdown* when module globals are liable to have been replaced by `None`.

__call__()

If *self* is alive then mark it as dead and return the result of calling `func(*args, **kwargs)`. If *self* is dead then return `None`.

detach()

If *self* is alive then mark it as dead and return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return `None`.

peek()

If *self* is alive then return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return `None`.

alive

Property which is true if the finalizer is alive, false otherwise.

atexit

A writable boolean property which by default is true. When the program exits, it calls all remaining live finalizers for which `atexit` is true. They are called in reverse order of creation.

> **Note**
>
> It is important to ensure that *func*, *args* and *kwargs* do not own any references to *obj*, either directly or indirectly, since otherwise *obj* will never be garbage collected. In particular, *func* should not be a bound method of *obj*.

Added in version 3.4.

weakref.**ReferenceType**

The type object for weak references objects.

weakref.**ProxyType**

The type object for proxies of objects which are not callable.

weakref.**CallableProxyType**

The type object for proxies of callable objects.

weakref.**ProxyTypes**

Sequence containing all the type objects for proxies. This can make it simpler to test if an object is a proxy without being dependent on naming both proxy types.

See also

PEP 205 - Weak References
The proposal and rationale for this feature, including links to earlier implementations and information about similar features in other languages.

8.9.1 Weak Reference Objects

Weak reference objects have no methods and no attributes besides *ref.__callback__*. A weak reference object allows the referent to be obtained, if it still exists, by calling it:

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

If the referent no longer exists, calling the reference object returns *None*:

```
>>> del o, o2
>>> print(r())
None
```

Testing that a weak reference object is still live should be done using the expression `ref() is not None`. Normally, application code that needs to use a reference object should follow this pattern:

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print("Object has been deallocated; can't frobnicate.")
else:
    print("Object is still live!")
    o.do_something_useful()
```

Using a separate test for "liveness" creates race conditions in threaded applications; another thread can cause a weak reference to become invalidated before the weak reference is called; the idiom shown above is safe in threaded applications as well as single-threaded applications.

Specialized versions of *ref* objects can be created through subclassing. This is used in the implementation of the *WeakValueDictionary* to reduce the memory overhead for each entry in the mapping. This may be most useful to associate additional information with a reference, but could also be used to insert additional processing on calls to retrieve the referent.

This example shows how a subclass of *ref* can be used to store additional information about an object and affect the value that's returned when the referent is accessed:

```
import weakref

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, /, **annotations):
        super().__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.items():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super().__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob
```

8.9.2 Example

This simple example shows how an application can use object IDs to retrieve objects that it has seen before. The IDs of the objects can then be used in other data structures without forcing the objects to remain alive, but the objects can still be retrieved by ID if they do.

```
import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]
```

8.9.3 Finalizer Objects

The main benefit of using *finalize* is that it makes it simple to register a callback without needing to preserve the returned finalizer object. For instance

```
>>> import weakref
>>> class Object:
...     pass
...
>>> kenny = Object()
>>> weakref.finalize(kenny, print, "You killed Kenny!")
<finalize object at ...; for 'Object' at ...>
>>> del kenny
You killed Kenny!
```

The finalizer can be called directly as well. However the finalizer will invoke the callback at most once.

```
>>> def callback(x, y, z):
...     print("CALLBACK")
...     return x + y + z
...
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> assert f.alive
>>> assert f() == 6
CALLBACK
>>> assert not f.alive
>>> f()                     # callback not called because finalizer dead
>>> del obj                 # callback not called because finalizer dead
```

You can unregister a finalizer using its *detach()* method. This kills the finalizer and returns the arguments passed to the constructor when it was created.

```
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> f.detach()
(<...Object object ...>, <function callback ...>, (1, 2), {'z': 3})
>>> newobj, func, args, kwargs = _
>>> assert not f.alive
>>> assert newobj is obj
>>> assert func(*args, **kwargs) == 6
CALLBACK
```

Unless you set the *atexit* attribute to *False*, a finalizer will be called when the program exits if it is still alive. For instance

```
>>> obj = Object()
>>> weakref.finalize(obj, print, "obj dead or exiting")
<finalize object at ...; for 'Object' at ...>
>>> exit()
obj dead or exiting
```

8.9.4 Comparing finalizers with `__del__()` methods

Suppose we want to create a class whose instances represent temporary directories. The directories should be deleted with their contents when the first of the following events occurs:

- the object is garbage collected,
- the object's `remove()` method is called, or
- the program exits.

We might try to implement the class using a `__del__()` method as follows:

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()

    def remove(self):
        if self.name is not None:
            shutil.rmtree(self.name)
            self.name = None

    @property
    def removed(self):
```

(continues on next page)

(continued from previous page)

```
        return self.name is None

    def __del__(self):
        self.remove()
```

Starting with Python 3.4, `__del__()` methods no longer prevent reference cycles from being garbage collected, and module globals are no longer forced to `None` during *interpreter shutdown*. So this code should work without any issues on CPython.

However, handling of `__del__()` methods is notoriously implementation specific, since it depends on internal details of the interpreter's garbage collector implementation.

A more robust alternative can be to define a finalizer which only references the specific functions and objects that it needs, rather than having access to the full state of the object:

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()
        self._finalizer = weakref.finalize(self, shutil.rmtree, self.name)

    def remove(self):
        self._finalizer()

    @property
    def removed(self):
        return not self._finalizer.alive
```

Defined like this, our finalizer only receives a reference to the details it needs to clean up the directory appropriately. If the object never gets garbage collected the finalizer will still be called at exit.

The other advantage of weakref based finalizers is that they can be used to register finalizers for classes where the definition is controlled by a third party, such as running code when a module is unloaded:

```
import weakref, sys
def unloading_module():
    # implicit reference to the module globals from the function body
weakref.finalize(sys.modules[__name__], unloading_module)
```

Note

If you create a finalizer object in a daemonic thread just as the program exits then there is the possibility that the finalizer does not get called at exit. However, in a daemonic thread *atexit.register()*, `try: ... finally: ...` and `with: ...` do not guarantee that cleanup occurs either.

8.10 `types` — Dynamic type creation and names for built-in types

Source code: Lib/types.py

This module defines utility functions to assist in dynamic creation of new types.

It also defines names for some object types that are used by the standard Python interpreter, but not exposed as builtins like *int* or *str* are.

Finally, it provides some additional type-related utility classes and functions that are not fundamental enough to be builtins.

8.10.1 Dynamic Type Creation

types.**new_class**(*name*, *bases=()*, *kwds=None*, *exec_body=None*)

Creates a class object dynamically using the appropriate metaclass.

The first three arguments are the components that make up a class definition header: the class name, the base classes (in order), the keyword arguments (such as `metaclass`).

The *exec_body* argument is a callback that is used to populate the freshly created class namespace. It should accept the class namespace as its sole argument and update the namespace directly with the class contents. If no callback is provided, it has the same effect as passing in `lambda ns: None`.

Added in version 3.3.

types.**prepare_class**(*name*, *bases=()*, *kwds=None*)

Calculates the appropriate metaclass and creates the class namespace.

The arguments are the components that make up a class definition header: the class name, the base classes (in order) and the keyword arguments (such as `metaclass`).

The return value is a 3-tuple: `metaclass, namespace, kwds`

metaclass is the appropriate metaclass, *namespace* is the prepared class namespace and *kwds* is an updated copy of the passed in *kwds* argument with any `'metaclass'` entry removed. If no *kwds* argument is passed in, this will be an empty dict.

Added in version 3.3.

Changed in version 3.6: The default value for the `namespace` element of the returned tuple has changed. Now an insertion-order-preserving mapping is used when the metaclass does not have a `__prepare__` method.

See also

metaclasses
Full details of the class creation process supported by these functions

PEP 3115 - Metaclasses in Python 3000
Introduced the `__prepare__` namespace hook

types.**resolve_bases**(*bases*)

Resolve MRO entries dynamically as specified by **PEP 560**.

This function looks for items in *bases* that are not instances of *type*, and returns a tuple where each such object that has an `__mro_entries__()` method is replaced with an unpacked result of calling this method. If a *bases* item is an instance of *type*, or it doesn't have an `__mro_entries__()` method, then it is included in the return tuple unchanged.

Added in version 3.7.

types.**get_original_bases**(*cls*, */*)

Return the tuple of objects originally given as the bases of *cls* before the `__mro_entries__()` method has been called on any bases (following the mechanisms laid out in **PEP 560**). This is useful for introspecting *Generics*.

For classes that have an `__orig_bases__` attribute, this function returns the value of `cls.__orig_bases__`. For classes without the `__orig_bases__` attribute, `cls.__bases__` is returned.

Examples:

```
from typing import TypeVar, Generic, NamedTuple, TypedDict

T = TypeVar("T")
class Foo(Generic[T]): ...
```

(continues on next page)

(continued from previous page)

```
class Bar(Foo[int], float): ...
class Baz(list[str]): ...
Eggs = NamedTuple("Eggs", [("a", int), ("b", str)])
Spam = TypedDict("Spam", {"a": int, "b": str})

assert Bar.__bases__ == (Foo, float)
assert get_original_bases(Bar) == (Foo[int], float)

assert Baz.__bases__ == (list,)
assert get_original_bases(Baz) == (list[str],)

assert Eggs.__bases__ == (tuple,)
assert get_original_bases(Eggs) == (NamedTuple,)

assert Spam.__bases__ == (dict,)
assert get_original_bases(Spam) == (TypedDict,)

assert int.__bases__ == (object,)
assert get_original_bases(int) == (object,)
```

Added in version 3.12.

See also

PEP 560 - Core support for typing module and generic types

8.10.2 Standard Interpreter Types

This module provides names for many of the types that are required to implement a Python interpreter. It deliberately avoids including some of the types that arise only incidentally during processing such as the `listiterator` type.

Typical use of these names is for *isinstance()* or *issubclass()* checks.

If you instantiate any of these types, note that signatures may vary between Python versions.

Standard names are defined for the following types:

types.**NoneType**

The type of *None*.

Added in version 3.10.

types.**FunctionType**

types.**LambdaType**

The type of user-defined functions and functions created by `lambda` expressions.

Raises an *auditing event* `function.__new__` with argument `code`.

The audit event only occurs for direct instantiation of function objects, and is not raised for normal compilation.

types.**GeneratorType**

The type of *generator*-iterator objects, created by generator functions.

types.**CoroutineType**

The type of *coroutine* objects, created by `async def` functions.

Added in version 3.5.

types.**AsyncGeneratorType**

The type of *asynchronous generator*-iterator objects, created by asynchronous generator functions.

Added in version 3.6.

class types.**CodeType**(***kwargs*)

The type of code objects such as returned by *compile()*.

Raises an *auditing event* `code.__new__` with arguments `code`, `filename`, `name`, `argcount`, `posonlyargcount`, `kwonlyargcount`, `nlocals`, `stacksize`, `flags`.

Note that the audited arguments may not match the names or positions required by the initializer. The audit event only occurs for direct instantiation of code objects, and is not raised for normal compilation.

types.**CellType**

The type for cell objects: such objects are used as containers for a function's *closure variables*.

Added in version 3.8.

types.**MethodType**

The type of methods of user-defined class instances.

types.**BuiltinFunctionType**

types.**BuiltinMethodType**

The type of built-in functions like *len()* or *sys.exit()*, and methods of built-in classes. (Here, the term "built-in" means "written in C".)

types.**WrapperDescriptorType**

The type of methods of some built-in data types and base classes such as `object.__init__()` or `object.__lt__()`.

Added in version 3.7.

types.**MethodWrapperType**

The type of *bound* methods of some built-in data types and base classes. For example it is the type of `object().__str__`.

Added in version 3.7.

types.**NotImplementedType**

The type of *NotImplemented*.

Added in version 3.10.

types.**MethodDescriptorType**

The type of methods of some built-in data types such as *str.join()*.

Added in version 3.7.

types.**ClassMethodDescriptorType**

The type of *unbound* class methods of some built-in data types such as `dict.__dict__['fromkeys']`.

Added in version 3.7.

class types.**ModuleType**(*name*, *doc=None*)

The type of *modules*. The constructor takes the name of the module to be created and optionally its *docstring*.

See also

Documentation on module objects
Provides details on the special attributes that can be found on instances of `ModuleType`.

importlib.util.module_from_spec()
Modules created using the `ModuleType` constructor are created with many of their special attributes unset or set to default values. `module_from_spec()` provides a more robust way of creating `ModuleType` instances which ensures the various attributes are set appropriately.

`types.`**`EllipsisType`**

The type of *`Ellipsis`*.

Added in version 3.10.

class `types.`**`GenericAlias`**(*t_origin*, *t_args*)

The type of *parameterized generics* such as `list[int]`.

`t_origin` should be a non-parameterized generic class, such as `list`, `tuple` or `dict`. `t_args` should be a *`tuple`* (possibly of length 1) of types which parameterize `t_origin`:

```
>>> from types import GenericAlias

>>> list[int] == GenericAlias(list, (int,))
True
>>> dict[str, int] == GenericAlias(dict, (str, int))
True
```

Added in version 3.9.

Changed in version 3.9.2: This type can now be subclassed.

See also

Generic Alias Types
In-depth documentation on instances of `types.GenericAlias`

PEP 585 - Type Hinting Generics In Standard Collections
Introducing the `types.GenericAlias` class

class `types.`**`UnionType`**

The type of *union type expressions*.

Added in version 3.10.

class `types.`**`TracebackType`**(*tb_next*, *tb_frame*, *tb_lasti*, *tb_lineno*)

The type of traceback objects such as found in `sys.exception().__traceback__`.

See the language reference for details of the available attributes and operations, and guidance on creating tracebacks dynamically.

`types.`**`FrameType`**

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

`types.`**`GetSetDescriptorType`**

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the *`property`* type, but for classes defined in extension modules.

`types.`**`MemberDescriptorType`**

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the *`property`* type, but for classes defined in extension modules.

In addition, when a class is defined with a `__slots__` attribute, then for each slot, an instance of `MemberDescriptorType` will be added as an attribute on the class. This allows the slot to appear in the class's `__dict__`.

CPython implementation detail: In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

class types.**MappingProxyType**(*mapping*)

Read-only proxy of a mapping. It provides a dynamic view on the mapping's entries, which means that when the mapping changes, the view reflects these changes.

Added in version 3.3.

Changed in version 3.9: Updated to support the new union (`|`) operator from **PEP 584**, which simply delegates to the underlying mapping.

key in proxy

Return `True` if the underlying mapping has a key *key*, else `False`.

proxy[key]

Return the item of the underlying mapping with key *key*. Raises a *KeyError* if *key* is not in the underlying mapping.

iter(proxy)

Return an iterator over the keys of the underlying mapping. This is a shortcut for `iter(proxy.keys())`.

len(proxy)

Return the number of items in the underlying mapping.

copy()

Return a shallow copy of the underlying mapping.

get(*key*[, *default*])

Return the value for *key* if *key* is in the underlying mapping, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a *KeyError*.

items()

Return a new view of the underlying mapping's items (`(key, value)` pairs).

keys()

Return a new view of the underlying mapping's keys.

values()

Return a new view of the underlying mapping's values.

reversed(proxy)

Return a reverse iterator over the keys of the underlying mapping.

Added in version 3.9.

hash(proxy)

Return a hash of the underlying mapping.

Added in version 3.12.

class types.**CapsuleType**

The type of capsule objects.

Added in version 3.13.

8.10.3 Additional Utility Classes and Functions

class types.**SimpleNamespace**

A simple *object* subclass that provides attribute access to its namespace, as well as a meaningful repr.

Unlike *object*, with SimpleNamespace you can add and remove attributes.

SimpleNamespace objects may be initialized in the same way as *dict*: either with keyword arguments, with a single positional argument, or with both. When initialized with keyword arguments, those are directly added to the underlying namespace. Alternatively, when initialized with a positional argument, the underlying namespace will be updated with key-value pairs from that argument (either a mapping object or an *iterable* object producing key-value pairs). All such keys must be strings.

The type is roughly equivalent to the following code:

```
class SimpleNamespace:
    def __init__(self, mapping_or_iterable=(), /, **kwargs):
        self.__dict__.update(mapping_or_iterable)
        self.__dict__.update(kwargs)

    def __repr__(self):
        items = (f"{k}={v!r}" for k, v in self.__dict__.items())
        return "{}({})".format(type(self).__name__, ", ".join(items))

    def __eq__(self, other):
        if isinstance(self, SimpleNamespace) and isinstance(other,␣
↪SimpleNamespace):
            return self.__dict__ == other.__dict__
        return NotImplemented
```

SimpleNamespace may be useful as a replacement for `class NS: pass`. However, for a structured record type use *namedtuple()* instead.

SimpleNamespace objects are supported by *copy.replace()*.

Added in version 3.3.

Changed in version 3.9: Attribute order in the repr changed from alphabetical to insertion (like dict).

Changed in version 3.13: Added support for an optional positional argument.

types.**DynamicClassAttribute**(*fget=None*, *fset=None*, *fdel=None*, *doc=None*)

Route attribute access on a class to __getattr__.

This is a descriptor, used to define attributes that act differently when accessed through an instance and through a class. Instance access remains normal, but access to an attribute through a class will be routed to the class's __getattr__ method; this is done by raising AttributeError.

This allows one to have properties active on an instance, and have virtual attributes on the class with the same name (see *enum.Enum* for an example).

Added in version 3.4.

8.10.4 Coroutine Utility Functions

types.**coroutine**(*gen_func*)

This function transforms a *generator* function into a *coroutine function* which returns a generator-based coroutine. The generator-based coroutine is still a *generator iterator*, but is also considered to be a *coroutine* object and is *awaitable*. However, it may not necessarily implement the `__await__()` method.

If *gen_func* is a generator function, it will be modified in-place.

If *gen_func* is not a generator function, it will be wrapped. If it returns an instance of *collections.abc.Generator*, the instance will be wrapped in an *awaitable* proxy object. All other types of objects will be returned as is.

Added in version 3.5.

8.11 copy — Shallow and deep copy operations

Source code: Lib/copy.py

Assignment statements in Python do not copy objects, they create bindings between a target and an object. For collections that are mutable or contain mutable items, a copy is sometimes needed so one can change one copy without changing the other. This module provides generic shallow and deep copy operations (explained below).

Interface summary:

copy.**copy**(*obj*)

Return a shallow copy of *obj*.

copy.**deepcopy**(*obj*[, *memo*])

Return a deep copy of *obj*.

copy.**replace**(*obj*, /, ***changes*)

Creates a new object of the same type as *obj*, replacing fields with values from *changes*.

Added in version 3.13.

exception copy.**Error**

Raised for module specific errors.

The difference between shallow and deep copying is only relevant for compound objects (objects that contain other objects, like lists or class instances):

- A *shallow copy* constructs a new compound object and then (to the extent possible) inserts *references* into it to the objects found in the original.
- A *deep copy* constructs a new compound object and then, recursively, inserts *copies* into it of the objects found in the original.

Two problems often exist with deep copy operations that don't exist with shallow copy operations:

- Recursive objects (compound objects that, directly or indirectly, contain a reference to themselves) may cause a recursive loop.
- Because deep copy copies everything it may copy too much, such as data which is intended to be shared between copies.

The *deepcopy()* function avoids these problems by:

- keeping a `memo` dictionary of objects already copied during the current copying pass; and
- letting user-defined classes override the copying operation or the set of components copied.

This module does not copy types like module, method, stack trace, stack frame, file, socket, window, or any similar types. It does "copy" functions and classes (shallow and deeply), by returning the original object unchanged; this is compatible with the way these are treated by the *pickle* module.

Shallow copies of dictionaries can be made using *dict.copy()*, and of lists by assigning a slice of the entire list, for example, `copied_list = original_list[:]`.

Classes can use the same interfaces to control copying that they use to control pickling. See the description of module *pickle* for information on these methods. In fact, the *copy* module uses the registered pickle functions from the *copyreg* module.

In order for a class to define its own copy implementation, it can define special methods *__copy__()* and *__deepcopy__()*.

object.**__copy__**(*self*)

Called to implement the shallow copy operation; no additional arguments are passed.

object.**__deepcopy__**(*self*, *memo*)

Called to implement the deep copy operation; it is passed one argument, the *memo* dictionary. If the `__deepcopy__` implementation needs to make a deep copy of a component, it should call the *deepcopy()* function with the component as first argument and the *memo* dictionary as second argument. The *memo* dictionary should be treated as an opaque object.

Function `copy.replace()` is more limited than *copy()* and *deepcopy()*, and only supports named tuples created by *namedtuple()*, *dataclasses*, and other classes which define method *__replace__()*.

object.**__replace__**(*self*, */*, ***changes*)

This method should create a new object of the same type, replacing fields with values from *changes*.

Added in version 3.13.

Module *pickle*
Discussion of the special methods used to support object state retrieval and restoration.

8.12 pprint — Data pretty printer

Source code: Lib/pprint.py

The *pprint* module provides a capability to "pretty-print" arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets or classes are included, as well as many other objects which are not representable as Python literals.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don't fit within the allowed width, adjustable by the *width* parameter defaulting to 80 characters.

Dictionaries are sorted by key before the display is computed.

Changed in version 3.9: Added support for pretty-printing *types.SimpleNamespace*.

Changed in version 3.10: Added support for pretty-printing *dataclasses.dataclass*.

8.12.1 Functions

pprint.**pp**(*object*, *stream=None*, *indent=1*, *width=80*, *depth=None*, *, *compact=False*, *sort_dicts=False*, *underscore_numbers=False*)

Prints the formatted representation of *object*, followed by a newline. This function may be used in the interactive interpreter instead of the *print()* function for inspecting values. Tip: you can reassign `print = pprint.pp` for use within a scope.

Parameters

- **object** – The object to be printed.
- **stream** (*file-like object* | None) – A file-like object to which the output will be written by calling its `write()` method. If `None` (the default), *sys.stdout* is used.
- **indent** (`int`) – The amount of indentation added for each nesting level.
- **width** (`int`) – The desired maximum number of characters per line in the output. If a structure cannot be formatted within the width constraint, a best effort will be made.
- **depth** (`int` | *None*) – The number of nesting levels which may be printed. If the data structure being printed is too deep, the next contained level is replaced by `...`. If `None` (the default), there is no constraint on the depth of the objects being formatted.

- **compact** (bool) – Control the way long *sequences* are formatted. If False (the default), each item of a sequence will be formatted on a separate line, otherwise as many items as will fit within the *width* will be formatted on each output line.
- **sort_dicts** (bool) – If True, dictionaries will be formatted with their keys sorted, otherwise they will be displayed in insertion order (the default).
- **underscore_numbers** (bool) – If True, integers will be formatted with the _ character for a thousands separator, otherwise underscores are not displayed (the default).

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pp(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
 'lumberjack',
 'knights',
 'ni']
```

Added in version 3.8.

pprint.**pprint**(*object*, *stream=None*, *indent=1*, *width=80*, *depth=None*, ***, *compact=False*, *sort_dicts=True*, *underscore_numbers=False*)

Alias for *pp()* with *sort_dicts* set to True by default, which would automatically sort the dictionaries' keys, you might want to use *pp()* instead where it is False by default.

pprint.**pformat**(*object*, *indent=1*, *width=80*, *depth=None*, ***, *compact=False*, *sort_dicts=True*, *underscore_numbers=False*)

Return the formatted representation of *object* as a string. *indent*, *width*, *depth*, *compact*, *sort_dicts* and *underscore_numbers* are passed to the *PrettyPrinter* constructor as formatting parameters and their meanings are as described in the documentation above.

pprint.**isreadable**(*object*)

Determine if the formatted representation of *object* is "readable", or can be used to reconstruct the value using *eval()*. This always returns False for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

pprint.**isrecursive**(*object*)

Determine if *object* requires a recursive representation. This function is subject to the same limitations as noted in *saferepr()* below and may raise an *RecursionError* if it fails to detect a recursive object.

pprint.**saferepr**(*object*)

Return a string representation of *object*, protected against recursion in some common data structures, namely instances of *dict*, *list* and *tuple* or subclasses whose __repr__ has not been overridden. If the representation of object exposes a recursive entry, the recursive reference will be represented as <Recursion on typename with id=number>. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
"[<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni
↪']"
```

8.12.2 PrettyPrinter Objects

class pprint.**PrettyPrinter**(*indent=1*, *width=80*, *depth=None*, *stream=None*, ***, *compact=False*, *sort_dicts=True*, *underscore_numbers=False*)

Construct a *PrettyPrinter* instance.

Arguments have the same meaning as for *pp()*. Note that they are in a different order, and that *sort_dicts* defaults to `True`.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[   ['spam', 'eggs', 'lumberjack', 'knights', 'ni'],
    'spam',
    'eggs',
    'lumberjack',
    'knights',
    'ni']
>>> pp = pprint.PrettyPrinter(width=41, compact=True)
>>> pp.pprint(stuff)
[['spam', 'eggs', 'lumberjack',
  'knights', 'ni'],
 'spam', 'eggs', 'lumberjack', 'knights',
 'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',)))))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...)))))))
```

Changed in version 3.4: Added the *compact* parameter.

Changed in version 3.8: Added the *sort_dicts* parameter.

Changed in version 3.10: Added the *underscore_numbers* parameter.

Changed in version 3.11: No longer attempts to write to `sys.stdout` if it is `None`.

PrettyPrinter instances have the following methods:

`PrettyPrinter.`**`pformat`**`(`*object*`)`

Return the formatted representation of *object*. This takes into account the options passed to the *PrettyPrinter* constructor.

`PrettyPrinter.`**`pprint`**`(`*object*`)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new *PrettyPrinter* objects don't need to be created.

`PrettyPrinter.`**`isreadable`**`(`*object*`)`

Determine if the formatted representation of the object is "readable," or can be used to reconstruct the value using *eval()*. Note that this returns `False` for recursive objects. If the *depth* parameter of the *PrettyPrinter* is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.`**`isrecursive`**`(`*object*`)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the *saferepr()* implementation.

`PrettyPrinter.`**`format`**`(`*object*, *context*, *maxlevels*, *level*`)`

Returns three values: the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The

second is a dictionary which contains the *id()* of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in *context*, the third return value should be `True`. Recursive calls to the *format()* method should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion; this will be `0` if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, *level*, gives the current level; recursive calls should be passed a value less than that of the current call.

8.12.3 Example

To demonstrate several uses of the *pp()* function and its parameters, let's fetch information about a project from PyPI:

```
>>> import json
>>> import pprint
>>> from urllib.request import urlopen
>>> with urlopen('https://pypi.org/pypi/sampleproject/1.2.0/json') as resp:
...     project_info = json.load(resp)['info']
```

In its basic form, *pp()* shows the whole object:

```
>>> pprint.pp(project_info)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': ['Development Status :: 3 - Alpha',
                 'Intended Audience :: Developers',
                 'License :: OSI Approved :: MIT License',
                 'Programming Language :: Python :: 2',
                 'Programming Language :: Python :: 2.6',
                 'Programming Language :: Python :: 2.7',

 'requires_dist': None,
 'requires_python': None,
 'summary': 'A sample Python project',
 'version': '1.2.0'}
```

The result can be limited to a certain *depth* (ellipsis is used for deeper contents):

```
>>> pprint.pp(project_info, depth=1)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': [...],
 'description': 'A sample Python project\n'
                '=======================\n'
                '\n'
                'This is the description file for the project.\n'
                '\n'
                'The file should use UTF-8 encoding and be written using '
                'ReStructured Text. It\n'
                'will be used to generate the project webpage on PyPI, and '
                'should be written for\n'
                'that purpose.\n'
                '\n'
                'Typical contents for this file would include an overview of '
                'the project, basic\n'
                'usage examples, etc. Generally, including the project '
                'changelog in here is not\n'
                'a good idea, although a simple "What\'s New" section for the '
                'most recent version\n'
                'may be appropriate.',
 'description_content_type': None,
 'docs_url': None,
 'download_url': 'UNKNOWN',
 'downloads': {...},
 'home_page': 'https://github.com/pypa/sampleproject',

 'requires_dist': None,
 'requires_python': None,
 'summary': 'A sample Python project',
 'version': '1.2.0'}
```

Additionally, maximum character *width* can be suggested. If a long object cannot be split, the specified width will be exceeded:

```
>>> pprint.pp(project_info, depth=1, width=60)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': [...],
 'description': 'A sample Python project\n'
                '=======================\n'
                '\n'
                'This is the description file for the '
                'project.\n'
                '\n'
                'The file should use UTF-8 encoding and be '
                'written using ReStructured Text. It\n'
                'will be used to generate the project '
                'webpage on PyPI, and should be written '
                'for\n'
                'that purpose.\n'
                '\n'
                'Typical contents for this file would '
                'include an overview of the project, '
                'basic\n'
                'usage examples, etc. Generally, including '
                'the project changelog in here is not\n'
                'a good idea, although a simple "What\'s '
                'New" section for the most recent version\n'
                'may be appropriate.',
 'description_content_type': None,
 'docs_url': None,
 'download_url': 'UNKNOWN',

```

8.13 reprlib — Alternate repr() implementation

Source code: Lib/reprlib.py

The reprlib module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

class reprlib.**Repr**(*, *maxlevel=6*, *maxtuple=6*, *maxlist=6*, *maxarray=5*, *maxdict=4*, *maxset=6*, *maxfrozenset=6*, *maxdeque=6*, *maxstring=30*, *maxlong=40*, *maxother=30*, *fillvalue='...'*, *indent=None*)

Class which provides formatting services useful in implementing functions similar to the built-in *repr()*; size limits for different object types are added to avoid the generation of representations which are excessively long.

The keyword arguments of the constructor can be used as a shortcut to set the attributes of the *Repr* instance. Which means that the following initialization:

```
aRepr = reprlib.Repr(maxlevel=3)
```

Is equivalent to:

```
aRepr = reprlib.Repr()
aRepr.maxlevel = 3
```

See section *Repr Objects* for more information about *Repr* attributes.

Changed in version 3.12: Allow attributes to be set via keyword arguments.

reprlib.**aRepr**

This is an instance of *Repr* which is used to provide the *repr()* function described below. Changing the attributes of this object will affect the size limits used by *repr()* and the Python debugger.

reprlib.**repr**(*obj*)

This is the *repr()* method of aRepr. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

In addition to size-limiting tools, the module also provides a decorator for detecting recursive calls to __repr__() and substituting a placeholder string instead.

@reprlib.**recursive_repr**(*fillvalue='...'*)

Decorator for __repr__() methods to detect recursive calls within the same thread. If a recursive call is made, the *fillvalue* is returned, otherwise, the usual __repr__() call is made. For example:

```
>>> from reprlib import recursive_repr
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
...         return '<' + '|'.join(map(repr, self)) + '>'
...
>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
>>> print(m)
<'a'|'b'|'c'|...|'x'>
```

Added in version 3.2.

8.13.1 Repr Objects

Repr instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

Repr.**fillvalue**

This string is displayed for recursive references. It defaults to `...`.

Added in version 3.11.

Repr.**maxlevel**

Depth limit on the creation of recursive representations. The default is `6`.

Repr.**maxdict**

Repr.**maxlist**

Repr.**maxtuple**

Repr.**maxset**

Repr.**maxfrozenset**

Repr.**maxdeque**

Repr.**maxarray**

Limits on the number of entries represented for the named object type. The default is `4` for *maxdict*, `5` for *maxarray*, and `6` for the others.

Repr.**maxlong**

Maximum number of characters in the representation for an integer. Digits are dropped from the middle. The default is `40`.

Repr.**maxstring**

Limit on the number of characters in the representation of the string. Note that the "normal" representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is `30`.

Repr.**maxother**

This limit is used to control the size of object types for which no specific formatting method is available on the *Repr* object. It is applied in a similar manner as *maxstring*. The default is `20`.

Repr.**indent**

If this attribute is set to `None` (the default), the output is formatted with no line breaks or indentation, like the standard *repr()*. For example:

```
>>> example = [
...     1, 'spam', {'a': 2, 'b': 'spam eggs', 'c': {3: 4.5, 6: []}}, 'ham']
>>> import reprlib
>>> aRepr = reprlib.Repr()
>>> print(aRepr.repr(example))
[1, 'spam', {'a': 2, 'b': 'spam eggs', 'c': {3: 4.5, 6: []}}, 'ham']
```

If *indent* is set to a string, each recursion level is placed on its own line, indented by that string:

```
>>> aRepr.indent = '-->'
>>> print(aRepr.repr(example))
[
-->1,
-->'spam',
-->{
-->-->'a': 2,
-->-->'b': 'spam eggs',
-->-->'c': {
-->-->-->3: 4.5,
```

(continues on next page)

(continued from previous page)

```
-->-->-->6: [],
-->-->},
-->},
-->'ham',
]
```

Setting *indent* to a positive integer value behaves as if it was set to a string with that number of spaces:

```
>>> aRepr.indent = 4
>>> print(aRepr.repr(example))
[
    1,
    'spam',
    {
        'a': 2,
        'b': 'spam eggs',
        'c': {
            3: 4.5,
            6: [],
        },
    },
    'ham',
]
```

Added in version 3.12.

Repr.**repr**(*obj*)

The equivalent to the built-in *repr()* that uses the formatting imposed by the instance.

Repr.**repr1**(*obj*, *level*)

Recursive implementation used by *repr()*. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call *repr1()* to perform recursive formatting, with `level - 1` for the value of *level* in the recursive call.

Repr.**repr_TYPE**(*obj*, *level*)

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by `'_'.join(type(obj).__name__.split())`. Dispatch to these methods is handled by *repr1()*. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

8.13.2 Subclassing Repr Objects

The use of dynamic dispatching by *Repr.repr1()* allows subclasses of *Repr* to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import reprlib
import sys

class MyRepr(reprlib.Repr):

    def repr_TextIOWrapper(self, obj, level):
        if obj.name in {'<stdin>', '<stdout>', '<stderr>'}:
            return obj.name
        return repr(obj)

aRepr = MyRepr()
print(aRepr.repr(sys.stdin))          # prints '<stdin>'
```

```
<stdin>
```

8.14 `enum` — Support for enumerations

Added in version 3.4.

Source code: Lib/enum.py

Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial
- Advanced Tutorial
- Enum Cookbook

An enumeration:

- is a set of symbolic names (members) bound to unique values
- can be iterated over to return its canonical (i.e. non-alias) members in definition order
- uses *call* syntax to return members by value
- uses *index* syntax to return members by name

Enumerations are created either by using `class` syntax, or by using function-call syntax:

```
>>> from enum import Enum

>>> # class syntax
>>> class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3

>>> # functional syntax
>>> Color = Enum('Color', [('RED', 1), ('GREEN', 2), ('BLUE', 3)])
```

Even though we can use `class` syntax to create Enums, Enums are not normal Python classes. See How are Enums different? for more details.

Note

Nomenclature

- The class `Color` is an *enumeration* (or *enum*)
- The attributes `Color.RED`, `Color.GREEN`, etc., are *enumeration members* (or *members*) and are functionally constants.
- The enum members have *names* and *values* (the name of `Color.RED` is `RED`, the value of `Color.BLUE` is `3`, etc.)

8.14.1 Module Contents

EnumType

The `type` for Enum and its subclasses.

Enum

Base class for creating enumerated constants.

IntEnum

Base class for creating enumerated constants that are also subclasses of *int*. (*Notes*)

StrEnum

Base class for creating enumerated constants that are also subclasses of *str*. (*Notes*)

Flag

Base class for creating enumerated constants that can be combined using the bitwise operations without losing their *Flag* membership.

IntFlag

Base class for creating enumerated constants that can be combined using the bitwise operators without losing their *IntFlag* membership. *IntFlag* members are also subclasses of *int*. (*Notes*)

ReprEnum

Used by *IntEnum*, *StrEnum*, and *IntFlag* to keep the *str()* of the mixed-in type.

EnumCheck

An enumeration with the values `CONTINUOUS`, `NAMED_FLAGS`, and `UNIQUE`, for use with *verify()* to ensure various constraints are met by a given enumeration.

FlagBoundary

An enumeration with the values `STRICT`, `CONFORM`, `EJECT`, and `KEEP` which allows for more fine-grained control over how invalid values are dealt with in an enumeration.

EnumDict

A subclass of *dict* for use when subclassing *EnumType*.

auto

Instances are replaced with an appropriate value for Enum members. *StrEnum* defaults to the lower-cased version of the member name, while other Enums default to 1 and increase from there.

property()

Allows *Enum* members to have attributes without conflicting with member names. The `value` and `name` attributes are implemented this way.

unique()

Enum class decorator that ensures only one name is bound to any one value.

verify()

Enum class decorator that checks user-selectable constraints on an enumeration.

member()

Make `obj` a member. Can be used as a decorator.

nonmember()

Do not make `obj` a member. Can be used as a decorator.

global_enum()

Modify the *str()* and *repr()* of an enum to show its members as belonging to the module instead of its class, and export the enum members to the global namespace.

show_flag_values()

Return a list of all power-of-two integers contained in a flag.

Added in version 3.6: `Flag`, `IntFlag`, `auto`

Added in version 3.11: `StrEnum`, `EnumCheck`, `ReprEnum`, `FlagBoundary`, `property`, `member`, `nonmember`, `global_enum`, `show_flag_values`

Added in version 3.13: `EnumDict`

8.14.2 Data Types

class enum.**EnumType**

EnumType is the *metaclass* for *enum* enumerations. It is possible to subclass *EnumType* – see Subclassing EnumType for details.

`EnumType` is responsible for setting the correct `__repr__()`, `__str__()`, `__format__()`, and `__reduce__()` methods on the final *enum*, as well as creating the enum members, properly handling duplicates, providing iteration over the enum class, etc.

__call__(*cls*, *value*, *names=None*, ***, *module=None*, *qualname=None*, *type=None*, *start=1*, *boundary=None*)

This method is called in two different ways:

- to look up an existing member:

  cls
  The enum class being called.

  value
  The value to lookup.

- to use the `cls` enum to create a new enum (only if the existing enum does not have any members):

  cls
  The enum class being called.

  value
  The name of the new Enum to create.

  names
  The names/values of the members for the new Enum.

  module
  The name of the module the new Enum is created in.

  qualname
  The actual location in the module where this Enum can be found.

  type
  A mix-in type for the new Enum.

  start
  The first integer value for the Enum (used by *auto*).

  boundary
  How to handle out-of-range values from bit operations (*Flag* only).

__contains__(*cls*, *member*)

Returns `True` if member belongs to the `cls`:

```
>>> some_var = Color.RED
>>> some_var in Color
True
>>> Color.RED.value in Color
True
```

Changed in version 3.12: Before Python 3.12, a `TypeError` is raised if a non-Enum-member is used in a containment check.

__dir__(*cls*)

Returns `['__class__', '__doc__', '__members__', '__module__']` and the names of the members in *cls*:

```
>>> dir(Color)
['BLUE', 'GREEN', 'RED', '__class__', '__contains__', '__doc__', '__
↪getitem__', '__init_subclass__', '__iter__', '__len__', '__members__', '_
↪_module__', '__name__', '__qualname__']
```

__getitem__(*cls*, *name*)

Returns the Enum member in *cls* matching *name*, or raises a *KeyError*:

```
>>> Color['BLUE']
<Color.BLUE: 3>
```

__iter__(*cls*)

Returns each member in *cls* in definition order:

```
>>> list(Color)
[<Color.RED: 1>, <Color.GREEN: 2>, <Color.BLUE: 3>]
```

__len__(*cls*)

Returns the number of member in *cls*:

```
>>> len(Color)
3
```

__members__

Returns a mapping of every enum name to its member, including aliases

__reversed__(*cls*)

Returns each member in *cls* in reverse definition order:

```
>>> list(reversed(Color))
[<Color.BLUE: 3>, <Color.GREEN: 2>, <Color.RED: 1>]
```

_add_alias_()

Adds a new name as an alias to an existing member. Raises a *NameError* if the name is already assigned to a different member.

_add_value_alias_()

Adds a new value as an alias to an existing member. Raises a *ValueError* if the value is already linked with a different member.

Added in version 3.11: Before 3.11 `EnumType` was called `EnumMeta`, which is still available as an alias.

class enum.**Enum**

Enum is the base class for all *enum* enumerations.

name

The name used to define the `Enum` member:

```
>>> Color.BLUE.name
'BLUE'
```

value

The value given to the `Enum` member:

```
>>> Color.RED.value
1
```

Value of the member, can be set in *__new__()*.

> **Note**
>
> Enum member values
>
> Member values can be anything: *int*, *str*, etc. If the exact value is unimportant you may use *auto* instances and an appropriate value will be chosen for you. See *auto* for the details.
>
> While mutable/unhashable values, such as *dict*, *list* or a mutable *dataclass*, can be used, they will have a quadratic performance impact during creation relative to the total number of mutable/unhashable values in the enum.

name

Name of the member.

value

Value of the member, can be set in *__new__()*.

order

No longer used, kept for backward compatibility. (class attribute, removed during class creation).

ignore

`_ignore_` is only used during creation and is removed from the enumeration once creation is complete.

`_ignore_` is a list of names that will not become members, and whose names will also be removed from the completed enumeration. See TimePeriod for an example.

__dir__(*self*)

Returns `['__class__', '__doc__', '__module__', 'name', 'value']` and any public methods defined on *self.__class__*:

```
>>> from datetime import date
>>> class Weekday(Enum):
...     MONDAY = 1
...     TUESDAY = 2
...     WEDNESDAY = 3
...     THURSDAY = 4
...     FRIDAY = 5
...     SATURDAY = 6
...     SUNDAY = 7
...     @classmethod
...     def today(cls):
...         print('today is %s' % cls(date.today().isoweekday()).name)
```

(continues on next page)

(continued from previous page)

```
...
>>> dir(Weekday.SATURDAY)
['__class__', '__doc__', '__eq__', '__hash__', '__module__', 'name', 'today
↪', 'value']
```

_generate_next_value_(*name*, *start*, *count*, *last_values*)

name
The name of the member being defined (e.g. 'RED').

start
The start value for the Enum; the default is 1.

count
The number of members currently defined, not including this one.

last_values
A list of the previous values.

A *staticmethod* that is used to determine the next value returned by `auto`:

```
>>> from enum import auto
>>> class PowersOfThree(Enum):
...     @staticmethod
...     def _generate_next_value_(name, start, count, last_values):
...         return 3 ** (count + 1)
...     FIRST = auto()
...     SECOND = auto()
...
>>> PowersOfThree.SECOND.value
9
```

__init__(*self*, **args*, ***kwds*)

By default, does nothing. If multiple values are given in the member assignment, those values become separate arguments to `__init__`; e.g.

```
>>> from enum import Enum
>>> class Weekday(Enum):
...     MONDAY = 1, 'Mon'
```

`Weekday.__init__()` would be called as `Weekday.__init__(self, 1, 'Mon')`

__init_subclass__(*cls*, ***kwds*)

A *classmethod* that is used to further configure subsequent subclasses. By default, does nothing.

missing(*cls*, *value*)

A *classmethod* for looking up values not found in *cls*. By default it does nothing, but can be overridden to implement custom search behavior:

```
>>> from enum import StrEnum
>>> class Build(StrEnum):
...     DEBUG = auto()
...     OPTIMIZED = auto()
...     @classmethod
...     def _missing_(cls, value):
...         value = value.lower()
...         for member in cls:
...             if member.value == value:
...                 return member
```

(continues on next page)

(continued from previous page)

```
...         return None
...
>>> Build.DEBUG.value
'debug'
>>> Build('deBUG')
<Build.DEBUG: 'debug'>
```

__new__ (*cls*, **args*, ***kwds*)

By default, doesn't exist. If specified, either in the enum class definition or in a mixin class (such as `int`), all values given in the member assignment will be passed; e.g.

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     TWENTYSIX = '1a', 16
```

results in the call `int('1a', 16)` and a value of `26` for the member.

Note

When writing a custom `__new__`, do not use `super().__new__` – call the appropriate `__new__` instead.

__repr__ (*self*)

Returns the string used for *repr()* calls. By default, returns the *Enum* name, member name, and value, but can be overridden:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __repr__(self):
...         cls_name = self.__class__.__name__
...         return f'{cls_name}.{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"{OtherStyle.
↪ALTERNATE}"
(OtherStyle.ALTERNATE, 'OtherStyle.ALTERNATE', 'OtherStyle.ALTERNATE')
```

__str__ (*self*)

Returns the string used for *str()* calls. By default, returns the *Enum* name and member name, but can be overridden:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __str__(self):
...         return f'{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"{OtherStyle.
↪ALTERNATE}"
(<OtherStyle.ALTERNATE: 1>, 'ALTERNATE', 'ALTERNATE')
```

__format__ (*self*)

Returns the string used for *format()* and *f-string* calls. By default, returns `__str__()` return value, but can be overridden:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __format__(self, spec):
...         return f'{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"{OtherStyle.
↪ALTERNATE}"
(<OtherStyle.ALTERNATE: 1>, 'OtherStyle.ALTERNATE', 'ALTERNATE')
```

Note

Using *auto* with *Enum* results in integers of increasing value, starting with `1`.

Changed in version 3.12: Added enum-dataclass-support

class enum.**IntEnum**

IntEnum is the same as *Enum*, but its members are also integers and can be used anywhere that an integer can be used. If any integer operation is performed with an *IntEnum* member, the resulting value loses its enumeration status.

```
>>> from enum import IntEnum
>>> class Number(IntEnum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...
>>> Number.THREE
<Number.THREE: 3>
>>> Number.ONE + Number.TWO
3
>>> Number.THREE + 5
8
>>> Number.THREE == 3
True
```

Note

Using *auto* with *IntEnum* results in integers of increasing value, starting with `1`.

Changed in version 3.11: `__str__()` is now `int.__str__()` to better support the *replacement of existing constants* use-case. `__format__()` was already `int.__format__()` for that same reason.

class enum.**StrEnum**

`StrEnum` is the same as *Enum*, but its members are also strings and can be used in most of the same places that a string can be used. The result of any string operation performed on or with a *StrEnum* member is not part of the enumeration.

Note

There are places in the stdlib that check for an exact *str* instead of a *str* subclass (i.e. `type(unknown) == str` instead of `isinstance(unknown, str)`), and in those locations you will need to use `str(StrEnum.member)`.

> **Note**
>
> Using `auto` with `StrEnum` results in the lower-cased member name as the value.

> **Note**
>
> `__str__()` is `str.__str__()` to better support the *replacement of existing constants* use-case. `__format__()` is likewise `str.__format__()` for that same reason.

Added in version 3.11.

class enum.**Flag**

`Flag` is the same as `Enum`, but its members support the bitwise operators `&` (*AND*), `|` (*OR*), `^` (*XOR*), and `~` (*INVERT*); the results of those operations are (aliases of) members of the enumeration.

__contains__(*self*, *value*)

Returns *True* if value is in self:

```
>>> from enum import Flag, auto
>>> class Color(Flag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> purple = Color.RED | Color.BLUE
>>> white = Color.RED | Color.GREEN | Color.BLUE
>>> Color.GREEN in purple
False
>>> Color.GREEN in white
True
>>> purple in white
True
>>> white in purple
False
```

__iter__(self):

Returns all contained non-alias members:

```
>>> list(Color.RED)
[<Color.RED: 1>]
>>> list(purple)
[<Color.RED: 1>, <Color.BLUE: 4>]
```

Added in version 3.11.

__len__(self):

Returns number of members in flag:

```
>>> len(Color.GREEN)
1
>>> len(white)
3
```

Added in version 3.11.

__bool__(self):

Returns *True* if any members in flag, *False* otherwise:

```
>>> bool(Color.GREEN)
True
>>> bool(white)
True
>>> black = Color(0)
>>> bool(black)
False
```

__or__ (*self*, *other*)

Returns current flag binary or'ed with other:

```
>>> Color.RED | Color.GREEN
<Color.RED|GREEN: 3>
```

__and__ (*self*, *other*)

Returns current flag binary and'ed with other:

```
>>> purple & white
<Color.RED|BLUE: 5>
>>> purple & Color.GREEN
<Color: 0>
```

__xor__ (*self*, *other*)

Returns current flag binary xor'ed with other:

```
>>> purple ^ white
<Color.GREEN: 2>
>>> purple ^ Color.GREEN
<Color.RED|GREEN|BLUE: 7>
```

__invert__(self):

Returns all the flags in *type(self)* that are not in *self*:

```
>>> ~white
<Color: 0>
>>> ~purple
<Color.GREEN: 2>
>>> ~Color.RED
<Color.GREEN|BLUE: 6>
```

_numeric_repr_()

Function used to format any remaining unnamed numeric values. Default is the value's repr; common choices are *hex()* and *oct()*.

> **Note**
>
> Using *auto* with *Flag* results in integers that are powers of two, starting with `1`.

Changed in version 3.11: The *repr()* of zero-valued flags has changed. It is now::

```
>>> Color(0)
<Color: 0>
```

class enum.**IntFlag**

`IntFlag` is the same as *Flag*, but its members are also integers and can be used anywhere that an integer can be used.

```
>>> from enum import IntFlag, auto
>>> class Color(IntFlag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> Color.RED & 2
<Color: 0>
>>> Color.RED | 2
<Color.RED|GREEN: 3>
```

If any integer operation is performed with an *IntFlag* member, the result is not an *IntFlag*:

```
>>> Color.RED + 2
3
```

If a *Flag* operation is performed with an *IntFlag* member and:

- the result is a valid *IntFlag*: an *IntFlag* is returned
- the result is not a valid *IntFlag*: the result depends on the *FlagBoundary* setting

The *repr()* of unnamed zero-valued flags has changed. It is now:

```
>>> Color(0)
<Color: 0>
```

Note

Using *auto* with *IntFlag* results in integers that are powers of two, starting with `1`.

Changed in version 3.11: `__str__()` is now `int.__str__()` to better support the *replacement of existing constants* use-case. `__format__()` was already `int.__format__()` for that same reason.

Inversion of an `IntFlag` now returns a positive value that is the union of all flags not in the given flag, rather than a negative value. This matches the existing *Flag* behavior.

class enum.**ReprEnum**

`ReprEnum` uses the *repr()* of *Enum*, but the *str()* of the mixed-in data type:

- `int.__str__()` for *IntEnum* and *IntFlag*
- `str.__str__()` for *StrEnum*

Inherit from `ReprEnum` to keep the *str()* / *format()* of the mixed-in data type instead of using the *Enum*-default *str()*.

Added in version 3.11.

class enum.**EnumCheck**

EnumCheck contains the options used by the *verify()* decorator to ensure various constraints; failed constraints result in a *ValueError*.

UNIQUE

Ensure that each value has only one name:

```
>>> from enum import Enum, verify, UNIQUE
>>> @verify(UNIQUE)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
```

(continues on next page)

(continued from previous page)

```
...     BLUE = 3
...     CRIMSON = 1
Traceback (most recent call last):
...
ValueError: aliases found in <enum 'Color'>: CRIMSON -> RED
```

CONTINUOUS

Ensure that there are no missing values between the lowest-valued member and the highest-valued member:

```
>>> from enum import Enum, verify, CONTINUOUS
>>> @verify(CONTINUOUS)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 5
Traceback (most recent call last):
...
ValueError: invalid enum 'Color': missing values 3, 4
```

NAMED_FLAGS

Ensure that any flag groups/masks contain only named flags – useful when values are specified instead of being generated by *auto()*:

```
>>> from enum import Flag, verify, NAMED_FLAGS
>>> @verify(NAMED_FLAGS)
... class Color(Flag):
...     RED = 1
...     GREEN = 2
...     BLUE = 4
...     WHITE = 15
...     NEON = 31
Traceback (most recent call last):
...
ValueError: invalid Flag 'Color': aliases WHITE and NEON are missing␣
↪combined values of 0x18 [use enum.show_flag_values(value) for details]
```

Note

CONTINUOUS and NAMED_FLAGS are designed to work with integer-valued members.

Added in version 3.11.

class enum.**FlagBoundary**

`FlagBoundary` controls how out-of-range values are handled in *Flag* and its subclasses.

STRICT

Out-of-range values cause a *ValueError* to be raised. This is the default for *Flag*:

```
>>> from enum import Flag, STRICT, auto
>>> class StrictFlag(Flag, boundary=STRICT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
```

(continues on next page)

(continued from previous page)

```
>>> StrictFlag(2**2 + 2**4)
Traceback (most recent call last):
...
ValueError: <flag 'StrictFlag'> invalid value 20
    given 0b0 10100
  allowed 0b0 00111
```

CONFORM

Out-of-range values have invalid values removed, leaving a valid *Flag* value:

```
>>> from enum import Flag, CONFORM, auto
>>> class ConformFlag(Flag, boundary=CONFORM):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> ConformFlag(2**2 + 2**4)
<ConformFlag.BLUE: 4>
```

EJECT

Out-of-range values lose their *Flag* membership and revert to *int*.

```
>>> from enum import Flag, EJECT, auto
>>> class EjectFlag(Flag, boundary=EJECT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> EjectFlag(2**2 + 2**4)
20
```

KEEP

Out-of-range values are kept, and the *Flag* membership is kept. This is the default for *IntFlag*:

```
>>> from enum import Flag, KEEP, auto
>>> class KeepFlag(Flag, boundary=KEEP):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> KeepFlag(2**2 + 2**4)
<KeepFlag.BLUE|16: 20>
```

Added in version 3.11.

class enum.**EnumDict**

EnumDict is a subclass of *dict* that is used as the namespace for defining enum classes (see prepare). It is exposed to allow subclasses of *EnumType* with advanced behavior like having multiple values per member. It should be called with the name of the enum class being created, otherwise private names and internal classes will not be handled correctly.

Note that only the *MutableMapping* interface (`__setitem__()` and *update()*) is overridden. It may be possible to bypass the checks using other `dict` operations like `|=`.

member_names

A list of member names.

Added in version 3.13.

Supported __dunder__ names

__members__ is a read-only ordered mapping of `member_name:member` items. It is only available on the class.

__new__(), if specified, must create and return the enum members; it is also a very good idea to set the member's `_value_` appropriately. Once all the members are created it is no longer used.

Supported _sunder_ names

- *_add_alias_()* – adds a new name as an alias to an existing member.
- *_add_value_alias_()* – adds a new value as an alias to an existing member.
- *_name_* – name of the member
- *_value_* – value of the member; can be set in `__new__`
- *_missing_()* – a lookup function used when a value is not found; may be overridden
- *_ignore_* – a list of names, either as a *list* or a *str*, that will not be transformed into members, and will be removed from the final class
- *_order_* – no longer used, kept for backward compatibility (class attribute, removed during class creation)
- *_generate_next_value_()* – used to get an appropriate value for an enum member; may be overridden

> **Note**
>
> For standard *Enum* classes the next value chosen is the highest value seen incremented by one.
>
> For *Flag* classes the next value chosen will be the next highest power-of-two.

- While `_sunder_` names are generally reserved for the further development of the *Enum* class and can not be used, some are explicitly allowed:
  - `_repr_*` (e.g. `_repr_html_`), as used in IPython's rich display

Added in version 3.6: `_missing_`, `_order_`, `_generate_next_value_`

Added in version 3.7: `_ignore_`

Added in version 3.13: `_add_alias_`, `_add_value_alias_`, `_repr_*`

8.14.3 Utilities and Decorators

class enum.**auto**

auto can be used in place of a value. If used, the *Enum* machinery will call an *Enum*'s *_generate_next_value_()* to get an appropriate value. For *Enum* and *IntEnum* that appropriate value will be the last value plus one; for *Flag* and *IntFlag* it will be the first power-of-two greater than the highest value; for *StrEnum* it will be the lower-cased version of the member's name. Care must be taken if mixing *auto()* with manually specified values.

auto instances are only resolved when at the top level of an assignment:

- `FIRST = auto()` will work (auto() is replaced with `1`);
- `SECOND = auto(), -2` will work (auto is replaced with `2`, so `2, -2` is used to create the `SECOND` enum member;
- `THREE = [auto(), -3]` will *not* work (`<auto instance>, -3` is used to create the `THREE` enum member)

Changed in version 3.11.1: In prior versions, `auto()` had to be the only thing on the assignment line to work properly.

`_generate_next_value_` can be overridden to customize the values used by *auto*.

> **Note**
>
> in 3.13 the default `_generate_next_value_` will always return the highest member value incremented by 1, and will fail if any member is an incompatible type.

`@enum.property`

A decorator similar to the built-in *property*, but specifically for enumerations. It allows member attributes to have the same names as members themselves.

> **Note**
>
> the *property* and the member must be defined in separate classes; for example, the *value* and *name* attributes are defined in the *Enum* class, and *Enum* subclasses can define members with the names `value` and `name`.

Added in version 3.11.

`@enum.unique`

A `class` decorator specifically for enumerations. It searches an enumeration's *__members__*, gathering any aliases it finds; if any are found *ValueError* is raised with the details:

```
>>> from enum import Enum, unique
>>> @unique
... class Mistake(Enum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...     FOUR = 3
...
Traceback (most recent call last):

ValueError: duplicate values found in <enum 'Mistake'>: FOUR -> THREE
```

`@enum.verify`

A `class` decorator specifically for enumerations. Members from *EnumCheck* are used to specify which constraints should be checked on the decorated enumeration.

Added in version 3.11.

`@enum.member`

A decorator for use in enums: its target will become a member.

Added in version 3.11.

`@enum.nonmember`

A decorator for use in enums: its target will not become a member.

Added in version 3.11.

`@enum.global_enum`

A decorator to change the *str()* and *repr()* of an enum to show its members as belonging to the module instead of its class. Should only be used when the enum members are exported to the module global namespace (see *re.RegexFlag* for an example).

Added in version 3.11.

enum.**show_flag_values**(*value*)

Return a list of all power-of-two integers contained in a flag *value*.

Added in version 3.11.

8.14.4 Notes

IntEnum, *StrEnum*, and *IntFlag*

These three enum types are designed to be drop-in replacements for existing integer- and string-based values; as such, they have extra limitations:

- `__str__` uses the value and not the name of the enum member
- `__format__`, because it uses `__str__`, will also use the value of the enum member instead of its name

If you do not need/want those limitations, you can either create your own base class by mixing in the `int` or `str` type yourself:

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     pass
```

or you can reassign the appropriate *str()*, etc., in your enum:

```
>>> from enum import Enum, IntEnum
>>> class MyIntEnum(IntEnum):
...     __str__ = Enum.__str__
```

8.15 `graphlib` — Functionality to operate with graph-like structures

Source code: Lib/graphlib.py

class graphlib.**TopologicalSorter**(*graph=None*)

Provides functionality to topologically sort a graph of *hashable* nodes.

A topological order is a linear ordering of the vertices in a graph such that for every directed edge u -> v from vertex u to vertex v, vertex u comes before vertex v in the ordering. For instance, the vertices of the graph may represent tasks to be performed, and the edges may represent constraints that one task must be performed before another; in this example, a topological ordering is just a valid sequence for the tasks. A complete topological ordering is possible if and only if the graph has no directed cycles, that is, if it is a directed acyclic graph.

If the optional *graph* argument is provided it must be a dictionary representing a directed acyclic graph where the keys are nodes and the values are iterables of all predecessors of that node in the graph (the nodes that have edges that point to the value in the key). Additional nodes can be added to the graph using the *add()* method.

In the general case, the steps required to perform the sorting of a given graph are as follows:

- Create an instance of the *TopologicalSorter* with an optional initial graph.
- Add additional nodes to the graph.
- Call *prepare()* on the graph.
- While *is_active()* is `True`, iterate over the nodes returned by *get_ready()* and process them. Call *done()* on each node as it finishes processing.

In case just an immediate sorting of the nodes in the graph is required and no parallelism is involved, the convenience method *TopologicalSorter.static_order()* can be used directly:

```
>>> graph = {"D": {"B", "C"}, "C": {"A"}, "B": {"A"}}
>>> ts = TopologicalSorter(graph)
>>> tuple(ts.static_order())
('A', 'C', 'B', 'D')
```

The class is designed to easily support parallel processing of the nodes as they become ready. For instance:

```
topological_sorter = TopologicalSorter()

# Add nodes to 'topological_sorter'...

topological_sorter.prepare()
while topological_sorter.is_active():
    for node in topological_sorter.get_ready():
        # Worker threads or processes take nodes to work on off the
        # 'task_queue' queue.
        task_queue.put(node)

    # When the work for a node is done, workers put the node in
    # 'finalized_tasks_queue' so we can get more nodes to work on.
    # The definition of 'is_active()' guarantees that, at this point, at
    # least one node has been placed on 'task_queue' that hasn't yet
    # been passed to 'done()', so this blocking 'get()' must (eventually)
    # succeed.  After calling 'done()', we loop back to call 'get_ready()'
    # again, so put newly freed nodes on 'task_queue' as soon as
    # logically possible.
    node = finalized_tasks_queue.get()
    topological_sorter.done(node)
```

add(*node*, **predecessors*)

Add a new node and its predecessors to the graph. Both the *node* and all elements in *predecessors* must be *hashable*.

If called multiple times with the same node argument, the set of dependencies will be the union of all dependencies passed in.

It is possible to add a node with no dependencies (*predecessors* is not provided) or to provide a dependency twice. If a node that has not been provided before is included among *predecessors* it will be automatically added to the graph with no predecessors of its own.

Raises *ValueError* if called after *prepare()*.

prepare()

Mark the graph as finished and check for cycles in the graph. If any cycle is detected, *CycleError* will be raised, but *get_ready()* can still be used to obtain as many nodes as possible until cycles block more progress. After a call to this function, the graph cannot be modified, and therefore no more nodes can be added using *add()*.

is_active()

Returns `True` if more progress can be made and `False` otherwise. Progress can be made if cycles do not block the resolution and either there are still nodes ready that haven't yet been returned by *TopologicalSorter.get_ready()* or the number of nodes marked *TopologicalSorter.done()* is less than the number that have been returned by *TopologicalSorter.get_ready()*.

The `__bool__()` method of this class defers to this function, so instead of:

```
if ts.is_active():
    ...
```

it is possible to simply do:

```
if ts:
    ...
```

Raises *ValueError* if called without calling *prepare()* previously.

done(**nodes*)

Marks a set of nodes returned by *TopologicalSorter.get_ready()* as processed, unblocking any successor of each node in *nodes* for being returned in the future by a call to *TopologicalSorter.get_ready()*.

Raises *ValueError* if any node in *nodes* has already been marked as processed by a previous call to this method or if a node was not added to the graph by using *TopologicalSorter.add()*, if called without calling *prepare()* or if node has not yet been returned by *get_ready()*.

get_ready()

Returns a `tuple` with all the nodes that are ready. Initially it returns all nodes with no predecessors, and once those are marked as processed by calling *TopologicalSorter.done()*, further calls will return all new nodes that have all their predecessors already processed. Once no more progress can be made, empty tuples are returned.

Raises *ValueError* if called without calling *prepare()* previously.

static_order()

Returns an iterator object which will iterate over nodes in a topological order. When using this method, *prepare()* and *done()* should not be called. This method is equivalent to:

```
def static_order(self):
    self.prepare()
    while self.is_active():
        node_group = self.get_ready()
        yield from node_group
        self.done(*node_group)
```

The particular order that is returned may depend on the specific order in which the items were inserted in the graph. For example:

```
>>> ts = TopologicalSorter()
>>> ts.add(3, 2, 1)
>>> ts.add(1, 0)
>>> print([*ts.static_order()])
[2, 0, 1, 3]

>>> ts2 = TopologicalSorter()
>>> ts2.add(1, 0)
>>> ts2.add(3, 2, 1)
>>> print([*ts2.static_order()])
[0, 2, 1, 3]
```

This is due to the fact that "0" and "2" are in the same level in the graph (they would have been returned in the same call to *get_ready()*) and the order between them is determined by the order of insertion.

If any cycle is detected, *CycleError* will be raised.

Added in version 3.9.

8.15.1 Exceptions

The *graphlib* module defines the following exception classes:

exception graphlib.**CycleError**

Subclass of *ValueError* raised by *TopologicalSorter.prepare()* if cycles exist in the working graph. If multiple cycles exist, only one undefined choice among them will be reported and included in the exception.

The detected cycle can be accessed via the second element in the *args* attribute of the exception instance and consists in a list of nodes, such that each node is, in the graph, an immediate predecessor of the next node in the list. In the reported list, the first and the last node will be the same, to make it clear that it is cyclic.

CHAPTER

NINE

NUMERIC AND MATHEMATICAL MODULES

The modules described in this chapter provide numeric and math-related functions and data types. The *numbers* module defines an abstract hierarchy of numeric types. The *math* and *cmath* modules contain various mathematical functions for floating-point and complex numbers. The *decimal* module supports exact representations of decimal numbers, using arbitrary precision arithmetic.

The following modules are documented in this chapter:

9.1 numbers — Numeric abstract base classes

Source code: Lib/numbers.py

The numbers module (**PEP 3141**) defines a hierarchy of numeric *abstract base classes* which progressively define more operations. None of the types defined in this module are intended to be instantiated.

class numbers.**Number**

The root of the numeric hierarchy. If you just want to check if an argument *x* is a number, without caring what kind, use `isinstance(x, Number)`.

9.1.1 The numeric tower

class numbers.**Complex**

Subclasses of this type describe complex numbers and include the operations that work on the built-in *complex* type. These are: conversions to *complex* and *bool*, *real*, *imag*, +, -, *, /, **, *abs()*, *conjugate()*, ==, and !=. All except - and != are abstract.

real

Abstract. Retrieves the real component of this number.

imag

Abstract. Retrieves the imaginary component of this number.

abstractmethod conjugate()

Abstract. Returns the complex conjugate. For example, `(1+3j).conjugate() == (1-3j)`.

class numbers.**Real**

To *Complex*, Real adds the operations that work on real numbers.

In short, those are: a conversion to *float*, *math.trunc()*, *round()*, *math.floor()*, *math.ceil()*, *divmod()*, //, %, <, <=, >, and >=.

Real also provides defaults for *complex()*, *real*, *imag*, and *conjugate()*.

class numbers.**Rational**

Subtypes *Real* and adds *numerator* and *denominator* properties. It also provides a default for *float()*.

The *numerator* and *denominator* values should be instances of *Integral* and should be in lowest terms with *denominator* positive.

numerator

Abstract.

denominator

Abstract.

class numbers.**Integral**

Subtypes *Rational* and adds a conversion to *int*. Provides defaults for *float()*, *numerator*, and *denominator*. Adds abstract methods for *pow()* with modulus and bit-string operations: <<, >>, &, ^, |, ~.

9.1.2 Notes for type implementers

Implementers should be careful to make equal numbers equal and hash them to the same values. This may be subtle if there are two different extensions of the real numbers. For example, *fractions.Fraction* implements *hash()* as follows:

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

Adding More Numeric ABCs

There are, of course, more possible ABCs for numbers, and this would be a poor hierarchy if it precluded the possibility of adding those. You can add `MyFoo` between *Complex* and *Real* with:

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

Implementing the arithmetic operations

We want to implement the arithmetic operations so that mixed-mode operations either call an implementation whose author knew about the types of both arguments, or convert both to the nearest built in type and do the operation there. For subtypes of *Integral*, this means that `__add__()` and `__radd__()` should be defined as:

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(self, other)
        else:
            return NotImplemented

    def __radd__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(other, self)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(other, self)
        elif isinstance(other, Integral):
```

(continues on next page)

(continued from previous page)

```
            return int(other) + int(self)
        elif isinstance(other, Real):
            return float(other) + float(self)
        elif isinstance(other, Complex):
            return complex(other) + complex(self)
        else:
            return NotImplemented
```

There are 5 different cases for a mixed-type operation on subclasses of *Complex*. I'll refer to all of the above code that doesn't refer to `MyIntegral` and `OtherTypeIKnowAbout` as "boilerplate". `a` will be an instance of `A`, which is a subtype of *Complex* (`a : A <: Complex`), and `b : B <: Complex`. I'll consider `a + b`:

1. If `A` defines an `__add__()` which accepts `b`, all is well.
2. If `A` falls back to the boilerplate code, and it were to return a value from `__add__()`, we'd miss the possibility that `B` defines a more intelligent `__radd__()`, so the boilerplate should return *NotImplemented* from `__add__()`. (Or `A` may not implement `__add__()` at all.)
3. Then `B`'s `__radd__()` gets a chance. If it accepts `a`, all is well.
4. If it falls back to the boilerplate, there are no more possible methods to try, so this is where the default implementation should live.
5. If `B <: A`, Python tries `B.__radd__` before `A.__add__`. This is ok, because it was implemented with knowledge of `A`, so it can handle those instances before delegating to *Complex*.

If `A <: Complex` and `B <: Real` without sharing any other knowledge, then the appropriate shared operation is the one involving the built in *complex*, and both `__radd__()` s land there, so `a+b == b+a`.

Because most of the operations on any given type will be very similar, it can be useful to define a helper function which generates the forward and reverse instances of any given operator. For example, *fractions.Fraction* uses:

```
def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__ + '__'
    forward.__doc__ = monomorphic_operator.__doc__

    def reverse(b, a):
        if isinstance(a, Rational):
            # Includes ints.
            return monomorphic_operator(a, b)
        elif isinstance(a, Real):
            return fallback_operator(float(a), float(b))
        elif isinstance(a, Complex):
            return fallback_operator(complex(a), complex(b))
        else:
            return NotImplemented
    reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
    reverse.__doc__ = monomorphic_operator.__doc__

    return forward, reverse
```

(continues on next page)

(continued from previous page)

```
def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...
```

9.2 `math` — Mathematical functions

This module provides access to common mathematical functions and constants, including those defined by the C standard.

These functions cannot be used with complex numbers; use the functions of the same name from the *cmath* module if you require support for complex numbers. The distinction between functions which support complex numbers and those which don't is made since most users do not want to learn quite as much mathematics as required to understand complex numbers. Receiving an exception instead of a complex result allows earlier detection of the unexpected complex number used as a parameter, so that the programmer can determine how and why it was generated in the first place.

The following functions are provided by this module. Except when explicitly noted otherwise, all return values are floats.

Number-theoretic functions	
comb(n, k)	Number of ways to choose *k* items from *n* items without repetition and wit
factorial(n)	*n* factorial
*gcd(*integers)*	Greatest common divisor of the integer arguments
isqrt(n)	Integer square root of a nonnegative integer *n*
*lcm(*integers)*	Least common multiple of the integer arguments
perm(n, k)	Number of ways to choose *k* items from *n* items without repetition and wit
Floating point arithmetic	
ceil(x)	Ceiling of *x*, the smallest integer greater than or equal to *x*
fabs(x)	Absolute value of *x*
floor(x)	Floor of *x*, the largest integer less than or equal to *x*
fma(x, y, z)	Fused multiply-add operation: `(x * y) + z`
fmod(x, y)	Remainder of division `x / y`
modf(x)	Fractional and integer parts of *x*
remainder(x, y)	Remainder of *x* with respect to *y*
trunc(x)	Integer part of *x*
Floating point manipulation functions	
copysign(x, y)	Magnitude (absolute value) of *x* with the sign of *y*
frexp(x)	Mantissa and exponent of *x*
isclose(a, b, rel_tol, abs_tol)	Check if the values *a* and *b* are close to each other
isfinite(x)	Check if *x* is neither an infinity nor a NaN
isinf(x)	Check if *x* is a positive or negative infinity
isnan(x)	Check if *x* is a NaN (not a number)
ldexp(x, i)	`x * (2**i)`, inverse of function *frexp()*
nextafter(x, y, steps)	Floating-point value *steps* steps after *x* towards *y*
ulp(x)	Value of the least significant bit of *x*
Power, exponential and logarithmic functions	
cbrt(x)	Cube root of *x*

continues on

Table 1 – continued from previous page

`exp(x)`	*e* raised to the power *x*
`exp2(x)`	*2* raised to the power *x*
`expm1(x)`	*e* raised to the power *x*, minus 1
`log(x, base)`	Logarithm of *x* to the given base (*e* by default)
`log1p(x)`	Natural logarithm of *1+x* (base *e*)
`log2(x)`	Base-2 logarithm of *x*
`log10(x)`	Base-10 logarithm of *x*
`pow(x, y)`	*x* raised to the power *y*
`sqrt(x)`	Square root of *x*
Summation and product functions	
`dist(p, q)`	Euclidean distance between two points *p* and *q* given as an iterable of coor
`fsum(iterable)`	Sum of values in the input *iterable*
`hypot(*coordinates)`	Euclidean norm of an iterable of coordinates
`prod(iterable, start)`	Product of elements in the input *iterable* with a *start* value
`sumprod(p, q)`	Sum of products from two iterables *p* and *q*
Angular conversion	
`degrees(x)`	Convert angle *x* from radians to degrees
`radians(x)`	Convert angle *x* from degrees to radians
Trigonometric functions	
`acos(x)`	Arc cosine of *x*
`asin(x)`	Arc sine of *x*
`atan(x)`	Arc tangent of *x*
`atan2(y, x)`	`atan(y / x)`
`cos(x)`	Cosine of *x*
`sin(x)`	Sine of *x*
`tan(x)`	Tangent of *x*
Hyperbolic functions	
`acosh(x)`	Inverse hyperbolic cosine of *x*
`asinh(x)`	Inverse hyperbolic sine of *x*
`atanh(x)`	Inverse hyperbolic tangent of *x*
`cosh(x)`	Hyperbolic cosine of *x*
`sinh(x)`	Hyperbolic sine of *x*
`tanh(x)`	Hyperbolic tangent of *x*
Special functions	
`erf(x)`	Error function at *x*
`erfc(x)`	Complementary error function at *x*
`gamma(x)`	Gamma function at *x*
`lgamma(x)`	Natural logarithm of the absolute value of the Gamma function at *x*
Constants	
`pi`	$\pi = 3.141592\ldots$
`e`	$e = 2.718281\ldots$
`tau`	$\tau = 2\pi = 6.283185\ldots$
`inf`	Positive infinity
`nan`	"Not a number" (NaN)

9.2.1 Number-theoretic functions

`math.`**`comb`**`(`*n*, *k*`)`

Return the number of ways to choose *k* items from *n* items without repetition and without order.

Evaluates to `n! / (k! * (n - k)!)` when `k <= n` and evaluates to zero when `k > n`.

Also called the binomial coefficient because it is equivalent to the coefficient of k-th term in polynomial expansion of `(1 + x)`^{n}.

Raises *`TypeError`* if either of the arguments are not integers. Raises *`ValueError`* if either of the arguments are negative.

Added in version 3.8.

math.**factorial**(*n*)

Return factorial of the nonnegative integer *n*.

Changed in version 3.10: Floats with integral values (like `5.0`) are no longer accepted.

math.**gcd**(**integers*)

Return the greatest common divisor of the specified integer arguments. If any of the arguments is nonzero, then the returned value is the largest positive integer that is a divisor of all arguments. If all arguments are zero, then the returned value is `0`. `gcd()` without arguments returns `0`.

Added in version 3.5.

Changed in version 3.9: Added support for an arbitrary number of arguments. Formerly, only two arguments were supported.

math.**isqrt**(*n*)

Return the integer square root of the nonnegative integer *n*. This is the floor of the exact square root of *n*, or equivalently the greatest integer *a* such that $a^2 \le n$.

For some applications, it may be more convenient to have the least integer *a* such that $n \le a^2$, or in other words the ceiling of the exact square root of *n*. For positive *n*, this can be computed using `a = 1 + isqrt(n - 1)`.

Added in version 3.8.

math.**lcm**(**integers*)

Return the least common multiple of the specified integer arguments. If all arguments are nonzero, then the returned value is the smallest positive integer that is a multiple of all arguments. If any of the arguments is zero, then the returned value is `0`. `lcm()` without arguments returns `1`.

Added in version 3.9.

math.**perm**(*n*, *k=None*)

Return the number of ways to choose *k* items from *n* items without repetition and with order.

Evaluates to `n! / (n - k)!` when `k <= n` and evaluates to zero when `k > n`.

If *k* is not specified or is `None`, then *k* defaults to *n* and the function returns `n!`.

Raises *TypeError* if either of the arguments are not integers. Raises *ValueError* if either of the arguments are negative.

Added in version 3.8.

9.2.2 Floating point arithmetic

math.**ceil**(*x*)

Return the ceiling of *x*, the smallest integer greater than or equal to *x*. If *x* is not a float, delegates to `x.__ceil__`, which should return an *Integral* value.

math.**fabs**(*x*)

Return the absolute value of *x*.

math.**floor**(*x*)

Return the floor of *x*, the largest integer less than or equal to *x*. If *x* is not a float, delegates to `x.__floor__`, which should return an *Integral* value.

math.**fma**(*x*, *y*, *z*)

Fused multiply-add operation. Return `(x * y) + z`, computed as though with infinite precision and range followed by a single round to the `float` format. This operation often provides better accuracy than the direct expression `(x * y) + z`.

This function follows the specification of the fusedMultiplyAdd operation described in the IEEE 754 standard. The standard leaves one case implementation-defined, namely the result of `fma(0, inf, nan)` and `fma(inf, 0, nan)`. In these cases, `math.fma` returns a NaN, and does not raise any exception.

Added in version 3.13.

`math.`**`fmod`**(*x*, *y*)

Return the floating-point remainder of `x / y`, as defined by the platform C library function `fmod(x, y)`. Note that the Python expression `x % y` may not return the same result. The intent of the C standard is that `fmod(x, y)` be exactly (mathematically; to infinite precision) equal to `x - n*y` for some integer *n* such that the result has the same sign as *x* and magnitude less than `abs(y)`. Python's `x % y` returns a result with the sign of *y* instead, and may not be exactly computable for float arguments. For example, `fmod(-1e-100, 1e100)` is `-1e-100`, but the result of Python's `-1e-100 % 1e100` is `1e100-1e-100`, which cannot be represented exactly as a float, and rounds to the surprising `1e100`. For this reason, function *fmod()* is generally preferred when working with floats, while Python's `x % y` is preferred when working with integers.

`math.`**`modf`**(*x*)

Return the fractional and integer parts of *x*. Both results carry the sign of *x* and are floats.

Note that *modf()* has a different call/return pattern than its C equivalents: it takes a single argument and return a pair of values, rather than returning its second return value through an 'output parameter' (there is no such thing in Python).

`math.`**`remainder`**(*x*, *y*)

Return the IEEE 754-style remainder of *x* with respect to *y*. For finite *x* and finite nonzero *y*, this is the difference `x - n*y`, where `n` is the closest integer to the exact value of the quotient `x / y`. If `x / y` is exactly halfway between two consecutive integers, the nearest *even* integer is used for `n`. The remainder `r = remainder(x, y)` thus always satisfies `abs(r) <= 0.5 * abs(y)`.

Special cases follow IEEE 754: in particular, `remainder(x, math.inf)` is *x* for any finite *x*, and `remainder(x, 0)` and `remainder(math.inf, x)` raise *ValueError* for any non-NaN *x*. If the result of the remainder operation is zero, that zero will have the same sign as *x*.

On platforms using IEEE 754 binary floating point, the result of this operation is always exactly representable: no rounding error is introduced.

Added in version 3.7.

`math.`**`trunc`**(*x*)

Return *x* with the fractional part removed, leaving the integer part. This rounds toward 0: `trunc()` is equivalent to *floor()* for positive *x*, and equivalent to *ceil()* for negative *x*. If *x* is not a float, delegates to `x.__trunc__`, which should return an *Integral* value.

For the *ceil()*, *floor()*, and *modf()* functions, note that *all* floating-point numbers of sufficiently large magnitude are exact integers. Python floats typically carry no more than 53 bits of precision (the same as the platform C double type), in which case any float *x* with `abs(x) >= 2**52` necessarily has no fractional bits.

9.2.3 Floating point manipulation functions

`math.`**`copysign`**(*x*, *y*)

Return a float with the magnitude (absolute value) of *x* but the sign of *y*. On platforms that support signed zeros, `copysign(1.0, -0.0)` returns *-1.0*.

`math.`**`frexp`**(*x*)

Return the mantissa and exponent of *x* as the pair `(m, e)`. *m* is a float and *e* is an integer such that `x == m * 2**e` exactly. If *x* is zero, returns `(0.0, 0)`, otherwise `0.5 <= abs(m) < 1`. This is used to "pick apart" the internal representation of a float in a portable way.

Note that *frexp()* has a different call/return pattern than its C equivalents: it takes a single argument and return a pair of values, rather than returning its second return value through an 'output parameter' (there is no such thing in Python).

math.**isclose**(*a*, *b*, *, *rel_tol=1e-09*, *abs_tol=0.0*)

Return `True` if the values *a* and *b* are close to each other and `False` otherwise.

Whether or not two values are considered close is determined according to given absolute and relative tolerances. If no errors occur, the result will be: `abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`.

rel_tol is the relative tolerance – it is the maximum allowed difference between *a* and *b*, relative to the larger absolute value of *a* or *b*. For example, to set a tolerance of 5%, pass `rel_tol=0.05`. The default tolerance is `1e-09`, which assures that the two values are the same within about 9 decimal digits. *rel_tol* must be nonnegative and less than `1.0`.

abs_tol is the absolute tolerance; it defaults to `0.0` and it must be nonnegative. When comparing `x` to `0.0`, `isclose(x, 0)` is computed as `abs(x) <= rel_tol * abs(x)`, which is `False` for any nonzero `x` and *rel_tol* less than `1.0`. So add an appropriate positive *abs_tol* argument to the call.

The IEEE 754 special values of `NaN`, `inf`, and `-inf` will be handled according to IEEE rules. Specifically, `NaN` is not considered close to any other value, including `NaN`. `inf` and `-inf` are only considered close to themselves.

Added in version 3.5.

See also

PEP 485 – A function for testing approximate equality

math.**isfinite**(*x*)

Return `True` if *x* is neither an infinity nor a NaN, and `False` otherwise. (Note that `0.0` *is* considered finite.)

Added in version 3.2.

math.**isinf**(*x*)

Return `True` if *x* is a positive or negative infinity, and `False` otherwise.

math.**isnan**(*x*)

Return `True` if *x* is a NaN (not a number), and `False` otherwise.

math.**ldexp**(*x*, *i*)

Return `x * (2**i)`. This is essentially the inverse of function *`frexp()`*.

math.**nextafter**(*x*, *y*, *steps=1*)

Return the floating-point value *steps* steps after *x* towards *y*.

If *x* is equal to *y*, return *y*, unless *steps* is zero.

Examples:

- `math.nextafter(x, math.inf)` goes up: towards positive infinity.
- `math.nextafter(x, -math.inf)` goes down: towards minus infinity.
- `math.nextafter(x, 0.0)` goes towards zero.
- `math.nextafter(x, math.copysign(math.inf, x))` goes away from zero.

See also *`math.ulp()`*.

Added in version 3.9.

Changed in version 3.12: Added the *steps* argument.

math.**ulp**(*x*)

Return the value of the least significant bit of the float *x*:

- If *x* is a NaN (not a number), return *x*.

- If *x* is negative, return `ulp(-x)`.
- If *x* is a positive infinity, return *x*.
- If *x* is equal to zero, return the smallest positive *denormalized* representable float (smaller than the minimum positive *normalized* float, *sys.float_info.min*).
- If *x* is equal to the largest positive representable float, return the value of the least significant bit of *x*, such that the first float smaller than *x* is `x - ulp(x)`.
- Otherwise (*x* is a positive finite number), return the value of the least significant bit of *x*, such that the first float bigger than *x* is `x + ulp(x)`.

ULP stands for "Unit in the Last Place".

See also *math.nextafter()* and *sys.float_info.epsilon*.

Added in version 3.9.

9.2.4 Power, exponential and logarithmic functions

`math.`**`cbrt`**`(`*x*`)`

Return the cube root of *x*.

Added in version 3.11.

`math.`**`exp`**`(`*x*`)`

Return *e* raised to the power *x*, where *e* = 2.718281… is the base of natural logarithms. This is usually more accurate than `math.e ** x` or `pow(math.e, x)`.

`math.`**`exp2`**`(`*x*`)`

Return *2* raised to the power *x*.

Added in version 3.11.

`math.`**`expm1`**`(`*x*`)`

Return *e* raised to the power *x*, minus 1. Here *e* is the base of natural logarithms. For small floats *x*, the subtraction in `exp(x) - 1` can result in a significant loss of precision; the *expm1()* function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1  # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5)    # result accurate to full precision
1.0000050000166668e-05
```

Added in version 3.2.

`math.`**`log`**`(`*x*`[,` *base* `])`

With one argument, return the natural logarithm of *x* (to base *e*).

With two arguments, return the logarithm of *x* to the given *base*, calculated as `log(x)/log(base)`.

`math.`**`log1p`**`(`*x*`)`

Return the natural logarithm of *1+x* (base *e*). The result is calculated in a way which is accurate for *x* near zero.

`math.`**`log2`**`(`*x*`)`

Return the base-2 logarithm of *x*. This is usually more accurate than `log(x, 2)`.

Added in version 3.3.

> **See also**
>
> *int.bit_length()* returns the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros.

math.**log10**(*x*)

Return the base-10 logarithm of *x*. This is usually more accurate than `log(x, 10)`.

math.**pow**(*x*, *y*)

Return *x* raised to the power *y*. Exceptional cases follow the IEEE 754 standard as far as possible. In particular, `pow(1.0, x)` and `pow(x, 0.0)` always return `1.0`, even when *x* is a zero or a NaN. If both *x* and *y* are finite, *x* is negative, and *y* is not an integer then `pow(x, y)` is undefined, and raises *ValueError*.

Unlike the built-in `**` operator, *math.pow()* converts both its arguments to type *float*. Use `**` or the built-in *pow()* function for computing exact integer powers.

Changed in version 3.11: The special cases `pow(0.0, -inf)` and `pow(-0.0, -inf)` were changed to return `inf` instead of raising *ValueError*, for consistency with IEEE 754.

math.**sqrt**(*x*)

Return the square root of *x*.

9.2.5 Summation and product functions

math.**dist**(*p*, *q*)

Return the Euclidean distance between two points *p* and *q*, each given as a sequence (or iterable) of coordinates. The two points must have the same dimension.

Roughly equivalent to:

```
sqrt(sum((px - qx) ** 2.0 for px, qx in zip(p, q)))
```

Added in version 3.8.

math.**fsum**(*iterable*)

Return an accurate floating-point sum of values in the iterable. Avoids loss of precision by tracking multiple intermediate partial sums.

The algorithm's accuracy depends on IEEE-754 arithmetic guarantees and the typical case where the rounding mode is half-even. On some non-Windows builds, the underlying C library uses extended precision addition and may occasionally double-round an intermediate sum causing it to be off in its least significant bit.

For further discussion and two alternative approaches, see the ASPN cookbook recipes for accurate floating-point summation.

math.**hypot**(**coordinates*)

Return the Euclidean norm, `sqrt(sum(x**2 for x in coordinates))`. This is the length of the vector from the origin to the point given by the coordinates.

For a two dimensional point `(x, y)`, this is equivalent to computing the hypotenuse of a right triangle using the Pythagorean theorem, `sqrt(x*x + y*y)`.

Changed in version 3.8: Added support for n-dimensional points. Formerly, only the two dimensional case was supported.

Changed in version 3.10: Improved the algorithm's accuracy so that the maximum error is under 1 ulp (unit in the last place). More typically, the result is almost always correctly rounded to within 1/2 ulp.

math.**prod**(*iterable*, *, *start=1*)

Calculate the product of all the elements in the input *iterable*. The default *start* value for the product is `1`.

When the iterable is empty, return the start value. This function is intended specifically for use with numeric values and may reject non-numeric types.

Added in version 3.8.

`math.`**`sumprod`**(*p*, *q*)

Return the sum of products of values from two iterables *p* and *q*.

Raises *ValueError* if the inputs do not have the same length.

Roughly equivalent to:

```
sum(itertools.starmap(operator.mul, zip(p, q, strict=True)))
```

For float and mixed int/float inputs, the intermediate products and sums are computed with extended precision.

Added in version 3.12.

9.2.6 Angular conversion

`math.`**`degrees`**(*x*)

Convert angle *x* from radians to degrees.

`math.`**`radians`**(*x*)

Convert angle *x* from degrees to radians.

9.2.7 Trigonometric functions

`math.`**`acos`**(*x*)

Return the arc cosine of *x*, in radians. The result is between `0` and `pi`.

`math.`**`asin`**(*x*)

Return the arc sine of *x*, in radians. The result is between `-pi/2` and `pi/2`.

`math.`**`atan`**(*x*)

Return the arc tangent of *x*, in radians. The result is between `-pi/2` and `pi/2`.

`math.`**`atan2`**(*y*, *x*)

Return `atan(y / x)`, in radians. The result is between `-pi` and `pi`. The vector in the plane from the origin to point `(x, y)` makes this angle with the positive X axis. The point of *atan2()* is that the signs of both inputs are known to it, so it can compute the correct quadrant for the angle. For example, `atan(1)` and `atan2(1, 1)` are both `pi/4`, but `atan2(-1, -1)` is `-3*pi/4`.

`math.`**`cos`**(*x*)

Return the cosine of *x* radians.

`math.`**`sin`**(*x*)

Return the sine of *x* radians.

`math.`**`tan`**(*x*)

Return the tangent of *x* radians.

9.2.8 Hyperbolic functions

Hyperbolic functions are analogs of trigonometric functions that are based on hyperbolas instead of circles.

`math.`**`acosh`**(*x*)

Return the inverse hyperbolic cosine of *x*.

`math.`**`asinh`**(*x*)

Return the inverse hyperbolic sine of *x*.

math.**atanh**(*x*)

Return the inverse hyperbolic tangent of *x*.

math.**cosh**(*x*)

Return the hyperbolic cosine of *x*.

math.**sinh**(*x*)

Return the hyperbolic sine of *x*.

math.**tanh**(*x*)

Return the hyperbolic tangent of *x*.

9.2.9 Special functions

math.**erf**(*x*)

Return the error function at *x*.

The *erf()* function can be used to compute traditional statistical functions such as the cumulative standard normal distribution:

```
def phi(x):
    'Cumulative distribution function for the standard normal distribution'
    return (1.0 + erf(x / sqrt(2.0))) / 2.0
```

Added in version 3.2.

math.**erfc**(*x*)

Return the complementary error function at *x*. The complementary error function is defined as `1.0 - erf(x)`. It is used for large values of *x* where a subtraction from one would cause a loss of significance.

Added in version 3.2.

math.**gamma**(*x*)

Return the Gamma function at *x*.

Added in version 3.2.

math.**lgamma**(*x*)

Return the natural logarithm of the absolute value of the Gamma function at *x*.

Added in version 3.2.

9.2.10 Constants

math.**pi**

The mathematical constant $\pi = 3.141592\ldots$, to available precision.

math.**e**

The mathematical constant $e = 2.718281\ldots$, to available precision.

math.**tau**

The mathematical constant $\tau = 6.283185\ldots$, to available precision. Tau is a circle constant equal to 2π, the ratio of a circle's circumference to its radius. To learn more about Tau, check out Vi Hart's video Pi is (still) Wrong, and start celebrating Tau day by eating twice as much pie!

Added in version 3.6.

math.**inf**

A floating-point positive infinity. (For negative infinity, use `-math.inf`.) Equivalent to the output of `float('inf')`.

Added in version 3.5.

math.**nan**

A floating-point "not a number" (NaN) value. Equivalent to the output of `float('nan')`. Due to the requirements of the IEEE-754 standard, `math.nan` and `float('nan')` are not considered to equal to any other numeric value, including themselves. To check whether a number is a NaN, use the *`isnan()`* function to test for NaNs instead of `is` or `==`. Example:

```
>>> import math
>>> math.nan == math.nan
False
>>> float('nan') == float('nan')
False
>>> math.isnan(math.nan)
True
>>> math.isnan(float('nan'))
True
```

Added in version 3.5.

Changed in version 3.11: It is now always available.

CPython implementation detail: The *`math`* module consists mostly of thin wrappers around the platform C math library functions. Behavior in exceptional cases follows Annex F of the C99 standard where appropriate. The current implementation will raise *`ValueError`* for invalid operations like `sqrt(-1.0)` or `log(0.0)` (where C99 Annex F recommends signaling invalid operation or divide-by-zero), and *`OverflowError`* for results that overflow (for example, `exp(1000.0)`). A NaN will not be returned from any of the functions above unless one or more of the input arguments was a NaN; in that case, most functions will return a NaN, but (again following C99 Annex F) there are some exceptions to this rule, for example `pow(float('nan'), 0.0)` or `hypot(float('nan'), float('inf'))`.

Note that Python makes no effort to distinguish signaling NaNs from quiet NaNs, and behavior for signaling NaNs remains unspecified. Typical behavior is to treat all NaNs as though they were quiet.

See also

Module *`cmath`*
Complex number versions of many of these functions.

9.3 `cmath` — Mathematical functions for complex numbers

This module provides access to mathematical functions for complex numbers. The functions in this module accept integers, floating-point numbers or complex numbers as arguments. They will also accept any Python object that has either a `__complex__()` or a `__float__()` method: these methods are used to convert the object to a complex or floating-point number, respectively, and the function is then applied to the result of the conversion.

Note

For functions involving branch cuts, we have the problem of deciding how to define those functions on the cut itself. Following Kahan's "Branch cuts for complex elementary functions" paper, as well as Annex G of C99 and later C standards, we use the sign of zero to distinguish one side of the branch cut from the other: for a branch cut along (a portion of) the real axis we look at the sign of the imaginary part, while for a branch cut along the imaginary axis we look at the sign of the real part.

For example, the *`cmath.sqrt()`* function has a branch cut along the negative real axis. An argument of `complex(-2.0, -0.0)` is treated as though it lies *below* the branch cut, and so gives a result on the negative imaginary axis:

```
>>> cmath.sqrt(complex(-2.0, -0.0))
-1.4142135623730951j
```

But an argument of `complex(-2.0, 0.0)` is treated as though it lies above the branch cut:

```
>>> cmath.sqrt(complex(-2.0, 0.0))
1.4142135623730951j
```

Conversions to and from polar coordinates	
phase(z)	Return the phase of z
polar(z)	Return the representation of z in polar coordinates
rect(r, phi)	Return the complex number z with polar coordinates r and *phi*
Power and logarithmic functions	
exp(z)	Return e raised to the power z
log(z[, base])	Return the logarithm of z to the given *base* (e by default)
log10(z)	Return the base-10 logarithm of z
sqrt(z)	Return the square root of z
Trigonometric functions	
acos(z)	Return the arc cosine of z
asin(z)	Return the arc sine of z
atan(z)	Return the arc tangent of z
cos(z)	Return the cosine of z
sin(z)	Return the sine of z
tan(z)	Return the tangent of z
Hyperbolic functions	
acosh(z)	Return the inverse hyperbolic cosine of z
asinh(z)	Return the inverse hyperbolic sine of z
atanh(z)	Return the inverse hyperbolic tangent of z
cosh(z)	Return the hyperbolic cosine of z
sinh(z)	Return the hyperbolic sine of z
tanh(z)	Return the hyperbolic tangent of z
Classification functions	
isfinite(z)	Check if all components of z are finite
isinf(z)	Check if any component of z is infinite
isnan(z)	Check if any component of z is a NaN
*isclose(a, b, *, rel_tol, abs_tol)*	Check if the values a and b are close to each other
Constants	
pi	$\pi = 3.141592\ldots$
e	$e = 2.718281\ldots$
tau	$\tau = 2\pi = 6.283185\ldots$
inf	Positive infinity
infj	Pure imaginary infinity
nan	"Not a number" (NaN)
nanj	Pure imaginary NaN

9.3.1 Conversions to and from polar coordinates

A Python complex number `z` is stored internally using *rectangular* or *Cartesian* coordinates. It is completely determined by its *real part* `z.real` and its *imaginary part* `z.imag`.

Polar coordinates give an alternative way to represent a complex number. In polar coordinates, a complex number z is defined by the modulus r and the phase angle *phi*. The modulus r is the distance from z to the origin, while the phase *phi* is the counterclockwise angle, measured in radians, from the positive x-axis to the line segment that joins the origin to z.

The following functions can be used to convert from the native rectangular coordinates to polar coordinates and back.

cmath.**phase**(*z*)

Return the phase of *z* (also known as the *argument* of *z*), as a float. `phase(z)` is equivalent to `math.atan2(z.imag, z.real)`. The result lies in the range [-π, π], and the branch cut for this operation lies along the negative real axis. The sign of the result is the same as the sign of `z.imag`, even when `z.imag` is zero:

```
>>> phase(complex(-1.0, 0.0))
3.141592653589793
>>> phase(complex(-1.0, -0.0))
-3.141592653589793
```

Note

The modulus (absolute value) of a complex number *z* can be computed using the built-in *abs()* function. There is no separate *cmath* module function for this operation.

cmath.**polar**(*z*)

Return the representation of *z* in polar coordinates. Returns a pair `(r, phi)` where *r* is the modulus of *z* and *phi* is the phase of *z*. `polar(z)` is equivalent to `(abs(z), phase(z))`.

cmath.**rect**(*r*, *phi*)

Return the complex number *z* with polar coordinates *r* and *phi*. Equivalent to `complex(r * math.cos(phi), r * math.sin(phi))`.

9.3.2 Power and logarithmic functions

cmath.**exp**(*z*)

Return *e* raised to the power *z*, where *e* is the base of natural logarithms.

cmath.**log**(*z*[, *base*])

Return the logarithm of *z* to the given *base*. If the *base* is not specified, returns the natural logarithm of *z*. There is one branch cut, from 0 along the negative real axis to -∞.

cmath.**log10**(*z*)

Return the base-10 logarithm of *z*. This has the same branch cut as *log()*.

cmath.**sqrt**(*z*)

Return the square root of *z*. This has the same branch cut as *log()*.

9.3.3 Trigonometric functions

cmath.**acos**(*z*)

Return the arc cosine of *z*. There are two branch cuts: One extends right from 1 along the real axis to ∞. The other extends left from -1 along the real axis to -∞.

cmath.**asin**(*z*)

Return the arc sine of *z*. This has the same branch cuts as *acos()*.

cmath.**atan**(*z*)

Return the arc tangent of *z*. There are two branch cuts: One extends from `1j` along the imaginary axis to ∞`j`. The other extends from $-$`1j` along the imaginary axis to $-\infty$`j`.

cmath.**cos**(*z*)

Return the cosine of *z*.

cmath.**sin**(*z*)

Return the sine of *z*.

cmath.**tan**(*z*)

Return the tangent of *z*.

9.3.4 Hyperbolic functions

cmath.**acosh**(*z*)

Return the inverse hyperbolic cosine of *z*. There is one branch cut, extending left from 1 along the real axis to -∞.

cmath.**asinh**(*z*)

Return the inverse hyperbolic sine of *z*. There are two branch cuts: One extends from `1j` along the imaginary axis to ∞`j`. The other extends from `-1j` along the imaginary axis to -∞`j`.

cmath.**atanh**(*z*)

Return the inverse hyperbolic tangent of *z*. There are two branch cuts: One extends from `1` along the real axis to ∞. The other extends from `-1` along the real axis to -∞.

cmath.**cosh**(*z*)

Return the hyperbolic cosine of *z*.

cmath.**sinh**(*z*)

Return the hyperbolic sine of *z*.

cmath.**tanh**(*z*)

Return the hyperbolic tangent of *z*.

9.3.5 Classification functions

cmath.**isfinite**(*z*)

Return `True` if both the real and imaginary parts of *z* are finite, and `False` otherwise.

Added in version 3.2.

cmath.**isinf**(*z*)

Return `True` if either the real or the imaginary part of *z* is an infinity, and `False` otherwise.

cmath.**isnan**(*z*)

Return `True` if either the real or the imaginary part of *z* is a NaN, and `False` otherwise.

cmath.**isclose**(*a*, *b*, ***, *rel_tol=1e-09*, *abs_tol=0.0*)

Return `True` if the values *a* and *b* are close to each other and `False` otherwise.

Whether or not two values are considered close is determined according to given absolute and relative tolerances. If no errors occur, the result will be: `abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`.

rel_tol is the relative tolerance – it is the maximum allowed difference between *a* and *b*, relative to the larger absolute value of *a* or *b*. For example, to set a tolerance of 5%, pass `rel_tol=0.05`. The default tolerance is `1e-09`, which assures that the two values are the same within about 9 decimal digits. *rel_tol* must be nonnegative and less than `1.0`.

abs_tol is the absolute tolerance; it defaults to `0.0` and it must be nonnegative. When comparing `x` to `0.0`, `isclose(x, 0)` is computed as `abs(x) <= rel_tol * abs(x)`, which is `False` for any `x` and rel_tol less than `1.0`. So add an appropriate positive abs_tol argument to the call.

The IEEE 754 special values of `NaN`, `inf`, and `-inf` will be handled according to IEEE rules. Specifically, `NaN` is not considered close to any other value, including `NaN`. `inf` and `-inf` are only considered close to themselves.

Added in version 3.5.

> **See also**
>
> **PEP 485** – A function for testing approximate equality

9.3.6 Constants

`cmath.pi`
: The mathematical constant π, as a float.

`cmath.e`
: The mathematical constant e, as a float.

`cmath.tau`
: The mathematical constant τ, as a float.

  Added in version 3.6.

`cmath.inf`
: Floating-point positive infinity. Equivalent to `float('inf')`.

  Added in version 3.6.

`cmath.infj`
: Complex number with zero real part and positive infinity imaginary part. Equivalent to `complex(0.0, float('inf'))`.

  Added in version 3.6.

`cmath.nan`
: A floating-point "not a number" (NaN) value. Equivalent to `float('nan')`.

  Added in version 3.6.

`cmath.nanj`
: Complex number with zero real part and NaN imaginary part. Equivalent to `complex(0.0, float('nan'))`.

  Added in version 3.6.

Note that the selection of functions is similar, but not identical, to that in module *math*. The reason for having two modules is that some users aren't interested in complex numbers, and perhaps don't even know what they are. They would rather have `math.sqrt(-1)` raise an exception than return a complex number. Also note that the functions defined in *cmath* always return a complex number, even if the answer can be expressed as a real number (in which case the complex number has an imaginary part of zero).

A note on branch cuts: They are curves along which the given function fails to be continuous. They are a necessary feature of many complex functions. It is assumed that if you need to compute with complex functions, you will understand about branch cuts. Consult almost any (not too elementary) book on complex variables for enlightenment. For information of the proper choice of branch cuts for numerical purposes, a good reference should be the following:

> **See also**
>
> Kahan, W: Branch cuts for complex elementary functions; or, Much ado about nothing's sign bit. In Iserles, A., and Powell, M. (eds.), The state of the art in numerical analysis. Clarendon Press (1987) pp165–211.

9.4 `decimal` — Decimal fixed-point and floating-point arithmetic

Source code: Lib/decimal.py

The *decimal* module provides support for fast correctly rounded decimal floating-point arithmetic. It offers several advantages over the *float* datatype:

- Decimal "is based on a floating-point model which was designed with people in mind, and necessarily has a paramount guiding principle – computers must provide an arithmetic that works in the same way as the arithmetic that people learn at school." – excerpt from the decimal arithmetic specification.
- Decimal numbers can be represented exactly. In contrast, numbers like `1.1` and `2.2` do not have exact representations in binary floating point. End users typically would not expect `1.1 + 2.2` to display as `3.3000000000000003` as it does with binary floating point.
- The exactness carries over into arithmetic. In decimal floating point, `0.1 + 0.1 + 0.1 - 0.3` is exactly equal to zero. In binary floating point, the result is `5.5511151231257827e-017`. While near to zero, the differences prevent reliable equality testing and differences can accumulate. For this reason, decimal is preferred in accounting applications which have strict equality invariants.
- The decimal module incorporates a notion of significant places so that `1.30 + 1.20` is `2.50`. The trailing zero is kept to indicate significance. This is the customary presentation for monetary applications. For multiplication, the "schoolbook" approach uses all the figures in the multiplicands. For instance, `1.3 * 1.2` gives `1.56` while `1.30 * 1.20` gives `1.5600`.
- Unlike hardware based binary floating point, the decimal module has a user alterable precision (defaulting to 28 places) which can be as large as needed for a given problem:

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571429')
```

- Both binary and decimal floating point are implemented in terms of published standards. While the built-in float type exposes only a modest portion of its capabilities, the decimal module exposes all required parts of the standard. When needed, the programmer has full control over rounding and signal handling. This includes an option to enforce exact arithmetic by using exceptions to block any inexact operations.
- The decimal module was designed to support "without prejudice, both exact unrounded decimal arithmetic (sometimes called fixed-point arithmetic) and rounded floating-point arithmetic." – excerpt from the decimal arithmetic specification.

The module design is centered around three concepts: the decimal number, the context for arithmetic, and signals.

A decimal number is immutable. It has a sign, coefficient digits, and an exponent. To preserve significance, the coefficient digits do not truncate trailing zeros. Decimals also include special values such as `Infinity`, `-Infinity`, and `NaN`. The standard also differentiates `-0` from `+0`.

The context for arithmetic is an environment specifying precision, rounding rules, limits on exponents, flags indicating the results of operations, and trap enablers which determine whether signals are treated as exceptions. Rounding options include *ROUND_CEILING*, *ROUND_DOWN*, *ROUND_FLOOR*, *ROUND_HALF_DOWN*, *ROUND_HALF_EVEN*, *ROUND_HALF_UP*, *ROUND_UP*, and *ROUND_05UP*.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are: *Clamped*, *InvalidOperation*, *DivisionByZero*, *Inexact*, *Rounded*, *Subnormal*, *Overflow*, *Underflow* and *FloatOperation*.

For each signal there is a flag and a trap enabler. When a signal is encountered, its flag is set to one, then, if the trap enabler is set to one, an exception is raised. Flags are sticky, so the user needs to reset them before monitoring a calculation.

9.4.1 Quick-start tutorial

The usual start to using decimals is importing the module, viewing the current context with *getcontext()* and, if necessary, setting new values for precision, rounding, or enabled traps:

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[Overflow, DivisionByZero,
        InvalidOperation])

>>> getcontext().prec = 7       # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as `NaN` which stands for "Not a number", positive and negative `Infinity`, and `-0`:

```
>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.140000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.4142135623730951')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.4142135623730950488801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')
```

If the *FloatOperation* signal is trapped, accidental mixing of decimals and floats in constructors or ordering comparisons raises an exception:

```
>>> c = getcontext()
>>> c.traps[FloatOperation] = True
>>> Decimal(3.14)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') < 3.7
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') == 3.5
True
```

Added in version 3.3.

The significance of a new Decimal is determined solely by the number of digits input. Context precision and rounding only come into play during arithmetic operations.

```
>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')
```

If the internal limits of the C version are exceeded, constructing a decimal raises *InvalidOperation*:

```
>>> Decimal("1e9999999999999999999")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.InvalidOperation: [<class 'decimal.InvalidOperation'>]
```

Changed in version 3.3.

Decimals interact well with much of the rest of Python. Here is a small decimal floating-point flying circus:

```
>>> data = list(map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split()))
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)
Decimal('1.3')
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')
```

And some mathematical functions are also available to Decimal:

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.4142135623730950488016887242')
>>> Decimal(1).exp()
Decimal('2.7182818284590452353602874713')
>>> Decimal('10').ln()
Decimal('2.3025850929940456840179914547')
>>> Decimal('10').log10()
```

(continues on next page)

(continued from previous page)

```
Decimal('1')
```

The *quantize()* method rounds a number to a fixed exponent. This method is useful for monetary applications that often round results to a fixed number of places:

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

As shown above, the *getcontext()* function accesses the current context and allows the settings to be changed. This approach meets the needs of most applications.

For more advanced work, it may be useful to create alternate contexts using the Context() constructor. To make an alternate active, use the *setcontext()* function.

In accordance with the standard, the *decimal* module provides two ready to use standard contexts, *BasicContext* and *ExtendedContext*. The former is especially useful for debugging because many of the traps are enabled:

```
>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

Contexts also have signal flags for monitoring exceptional conditions encountered during computations. The flags remain set until explicitly cleared, so it is best to clear the flags before each set of monitored computations by using the *clear_flags()* method.

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[Inexact, Rounded], traps=[])
```

The *flags* entry shows that the rational approximation to pi was rounded (digits beyond the context precision were thrown away) and that the result is inexact (some of the discarded digits were non-zero).

Individual traps are set using the dictionary in the *traps* attribute of a context:

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
```

(continues on next page)

(continued from previous page)

```
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

Most programs adjust the current context only once, at the beginning of the program. And, in many applications, data is converted to *Decimal* with a single cast inside a loop. With context set and decimals created, the bulk of the program manipulates the data no differently than with other Python numeric types.

9.4.2 Decimal objects

class decimal.**Decimal**(*value='0'*, *context=None*)

Construct a new *Decimal* object based from *value*.

value can be an integer, string, tuple, *float*, or another *Decimal* object. If no *value* is given, returns `Decimal('0')`. If *value* is a string, it should conform to the decimal numeric string syntax after leading and trailing whitespace characters, as well as underscores throughout, are removed:

```
sign           ::=  '+' | '-'
digit          ::=  '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator      ::=  'e' | 'E'
digits         ::=  digit [digit]...
decimal-part   ::=  digits '.' [digits] | ['.'] digits
exponent-part  ::=  indicator [sign] digits
infinity       ::=  'Infinity' | 'Inf'
nan            ::=  'NaN' [digits] | 'sNaN' [digits]
numeric-value  ::=  decimal-part [exponent-part] | infinity
numeric-string ::=  [sign] numeric-value | [sign] nan
```

Other Unicode decimal digits are also permitted where `digit` appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits `'\uff10'` through `'\uff19'`. Case is not significant, so, for example, `inf`, `Inf`, `INFINITY`, and `iNfINity` are all acceptable spellings for positive infinity.

If *value* is a *tuple*, it should have three components, a sign (`0` for positive or `1` for negative), a *tuple* of digits, and an integer exponent. For example, `Decimal((0, (1, 4, 1, 4), -3))` returns `Decimal('1.414')`.

If *value* is a *float*, the binary floating-point value is losslessly converted to its exact decimal equivalent. This conversion can often require 53 or more digits of precision. For example, `Decimal(float('1.1'))` converts to `Decimal('1.100000000000000088817841970012523233890533447265625')`.

The *context* precision does not affect how many digits are stored. That is determined exclusively by the number of digits in *value*. For example, `Decimal('3.00000')` records all five zeros even if the context precision is only three.

The purpose of the *context* argument is determining what to do if *value* is a malformed string. If the context traps *InvalidOperation*, an exception is raised; otherwise, the constructor returns a new Decimal with the value of `NaN`.

Once constructed, *Decimal* objects are immutable.

Changed in version 3.2: The argument to the constructor is now permitted to be a *float* instance.

Changed in version 3.3: *float* arguments raise an exception if the *FloatOperation* trap is set. By default the trap is off.

Changed in version 3.6: Underscores are allowed for grouping, as with integral and floating-point literals in code.

Decimal floating-point objects share many properties with the other built-in numeric types such as *float* and *int*. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as *float* or *int*).

There are some small differences between arithmetic on Decimal objects and arithmetic on integers and floats. When the remainder operator `%` is applied to Decimal objects, the sign of the result is the sign of the *dividend* rather than the sign of the divisor:

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

The integer division operator `//` behaves analogously, returning the integer part of the true quotient (truncating towards zero) rather than its floor, so as to preserve the usual identity `x == (x // y) * y + x % y`:

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

The `%` and `//` operators implement the `remainder` and `divide-integer` operations (respectively) as described in the specification.

Decimal objects cannot generally be combined with floats or instances of *fractions.Fraction* in arithmetic operations: an attempt to add a *Decimal* to a *float*, for example, will raise a *TypeError*. However, it is possible to use Python's comparison operators to compare a *Decimal* instance `x` with another number `y`. This avoids confusing results when doing equality comparisons between numbers of different types.

Changed in version 3.2: Mixed-type comparisons between *Decimal* instances and other numeric types are now fully supported.

In addition to the standard numeric properties, decimal floating-point objects also have a number of specialized methods:

adjusted()

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains: `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

as_integer_ratio()

Return a pair `(n, d)` of integers that represent the given *Decimal* instance as a fraction, in lowest terms and with a positive denominator:

```
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```

The conversion is exact. Raise OverflowError on infinities and ValueError on NaNs.

Added in version 3.6.

as_tuple()

Return a *named tuple* representation of the number: `DecimalTuple(sign, digits, exponent)`.

canonical()

Return the canonical encoding of the argument. Currently, the encoding of a *Decimal* instance is always canonical, so this operation returns its argument unchanged.

compare(*other*, *context=None*)

Compare the values of two Decimal instances. *compare()* returns a Decimal instance, and if either operand is a NaN then the result is a NaN:

```
a or b is a NaN  ==> Decimal('NaN')
a < b            ==> Decimal('-1')
a == b           ==> Decimal('0')
a > b            ==> Decimal('1')
```

compare_signal(*other*, *context=None*)

This operation is identical to the *compare()* method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

compare_total(*other*, *context=None*)

Compare two operands using their abstract representation rather than their numerical value. Similar to the *compare()* method, but the result gives a total ordering on *Decimal* instances. Two *Decimal* instances with the same numeric value but different representations compare unequal in this ordering:

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is `Decimal('0')` if both operands have the same representation, `Decimal('-1')` if the first operand is lower in the total order than the second, and `Decimal('1')` if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

compare_total_mag(*other*, *context=None*)

Compare two operands using their abstract representation rather than their value as in *compare_total()*, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

conjugate()

Just returns self, this method is only to comply with the Decimal Specification.

copy_abs()

Return the absolute value of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

copy_negate()

Return the negation of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

copy_sign(*other*, *context=None*)

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example:

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

exp(*context=None*)

Return the value of the (natural) exponential function `e**x` at the given number. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

classmethod from_float(*f*)

Alternative constructor that only accepts instances of *float* or *int*.

Note `Decimal.from_float(0.1)` is not the same as `Decimal('0.1')`. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is `0x1.999999999999ap-4`. That equivalent value in decimal is `0.1000000000000000055511151231257827021181583404541015625`.

Note

From Python 3.2 onwards, a *Decimal* instance can also be constructed directly from a *float*.

```
>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

Added in version 3.1.

fma(*other*, *third*, *context=None*)

Fused multiply-add. Return self*other+third with no rounding of the intermediate product self*other.

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

is_canonical()

Return *True* if the argument is canonical and *False* otherwise. Currently, a *Decimal* instance is always canonical, so this operation always returns *True*.

is_finite()

Return *True* if the argument is a finite number, and *False* if the argument is an infinity or a NaN.

is_infinite()

Return *True* if the argument is either positive or negative infinity and *False* otherwise.

is_nan()

Return *True* if the argument is a (quiet or signaling) NaN and *False* otherwise.

is_normal(*context=None*)

Return *True* if the argument is a *normal* finite number. Return *False* if the argument is zero, subnormal, infinite or a NaN.

is_qnan()

Return *True* if the argument is a quiet NaN, and *False* otherwise.

is_signed()

Return *True* if the argument has a negative sign and *False* otherwise. Note that zeros and NaNs can both carry signs.

is_snan()

Return *True* if the argument is a signaling NaN and *False* otherwise.

is_subnormal(*context=None*)

Return *True* if the argument is subnormal, and *False* otherwise.

is_zero()

Return *True* if the argument is a (positive or negative) zero and *False* otherwise.

ln(*context=None*)

Return the natural (base e) logarithm of the operand. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

log10(*context=None*)

Return the base ten logarithm of the operand. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

logb(*context=None*)

For a nonzero number, return the adjusted exponent of its operand as a *Decimal* instance. If the operand is a zero then `Decimal('-Infinity')` is returned and the *DivisionByZero* flag is raised. If the operand is an infinity then `Decimal('Infinity')` is returned.

logical_and(*other*, *context=None*)

logical_and() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise `and` of the two operands.

logical_invert(*context=None*)

logical_invert() is a logical operation. The result is the digit-wise inversion of the operand.

logical_or(*other*, *context=None*)

logical_or() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise `or` of the two operands.

logical_xor(*other*, *context=None*)

logical_xor() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

max(*other*, *context=None*)

Like `max(self, other)` except that the context rounding rule is applied before returning and that `NaN` values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

max_mag(*other*, *context=None*)

Similar to the *max()* method, but the comparison is done using the absolute values of the operands.

min(*other*, *context=None*)

Like `min(self, other)` except that the context rounding rule is applied before returning and that `NaN` values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

min_mag(*other*, *context=None*)

Similar to the *min()* method, but the comparison is done using the absolute values of the operands.

next_minus(*context=None*)

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

next_plus(*context=None*)

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

next_toward(*other*, *context=None*)

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

normalize(*context=None*)

Used for producing canonical values of an equivalence class within either the current context or the specified context.

This has the same semantics as the unary plus operation, except that if the final result is finite it is reduced to its simplest form, with all trailing zeros removed and its sign preserved. That is, while the coefficient is non-zero and a multiple of ten the coefficient is divided by ten and the exponent is incremented by 1. Otherwise (the coefficient is zero) the exponent is set to 0. In all cases the sign is unchanged.

For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

Note that rounding is applied *before* reducing to simplest form.

In the latest versions of the specification, this operation is also known as `reduce`.

number_class(*context=None*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.
- `"-Normal"`, indicating that the operand is a negative normal number.
- `"-Subnormal"`, indicating that the operand is negative and subnormal.
- `"-Zero"`, indicating that the operand is a negative zero.
- `"+Zero"`, indicating that the operand is a positive zero.
- `"+Subnormal"`, indicating that the operand is positive and subnormal.
- `"+Normal"`, indicating that the operand is a positive normal number.
- `"+Infinity"`, indicating that the operand is positive infinity.
- `"NaN"`, indicating that the operand is a quiet NaN (Not a Number).
- `"sNaN"`, indicating that the operand is a signaling NaN.

quantize(*exp*, *rounding=None*, *context=None*)

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an *InvalidOperation* is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the `rounding` argument if given, else by the given `context` argument; if neither argument is given the rounding mode of the current thread's context is used.

An error is returned whenever the resulting exponent is greater than *Emax* or less than *Etiny()*.

radix()

Return `Decimal(10)`, the radix (base) in which the *Decimal* class does all its arithmetic. Included for compatibility with the specification.

remainder_near(*other*, *context=None*)

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where `n` is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

rotate(*other*, *context=None*)

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length precision if necessary. The sign and exponent of the first operand are unchanged.

same_quantum(*other*, *context=None*)

Test whether self and other have the same exponent or whether both are `NaN`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

scaleb(*other*, *context=None*)

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by `10**other`. The second operand must be an integer.

shift(*other*, *context=None*)

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

sqrt(*context=None*)

Return the square root of the argument to full precision.

to_eng_string(*context=None*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

to_integral(*rounding=None*, *context=None*)

Identical to the *to_integral_value()* method. The `to_integral` name has been kept for compatibility with older versions.

to_integral_exact(*rounding=None*, *context=None*)

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

to_integral_value(*rounding=None*, *context=None*)

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

Decimal numbers can be rounded using the *round()* function:

round(number)

round(number, ndigits)

If *ndigits* is not given or `None`, returns the nearest *int* to *number*, rounding ties to even, and ignoring the rounding mode of the *Decimal* context. Raises *OverflowError* if *number* is an infinity or *ValueError* if it is a (quiet or signaling) NaN.

If *ndigits* is an *int*, the context's rounding mode is respected and a *Decimal* representing *number* rounded to the nearest multiple of `Decimal('1E-ndigits')` is returned; in this case, `round(number, ndigits)` is equivalent to `self.quantize(Decimal('1E-ndigits'))`. Returns `Decimal('NaN')` if *number* is a quiet NaN. Raises *InvalidOperation* if *number* is an infinity, a signaling NaN, or if the length of the coefficient after the quantize operation would be greater than the current context's precision. In other words, for the non-corner cases:

- if *ndigits* is positive, return *number* rounded to *ndigits* decimal places;
- if *ndigits* is zero, return *number* rounded to the nearest integer;
- if *ndigits* is negative, return *number* rounded to the nearest multiple of `10**abs(ndigits)`.

For example:

```
>>> from decimal import Decimal, getcontext, ROUND_DOWN
>>> getcontext().rounding = ROUND_DOWN
>>> round(Decimal('3.75'))      # context rounding ignored
4
>>> round(Decimal('3.5'))       # round-ties-to-even
4
>>> round(Decimal('3.75'), 0)   # uses the context rounding
Decimal('3')
>>> round(Decimal('3.75'), 1)
Decimal('3.7')
>>> round(Decimal('3.75'), -1)
Decimal('0E+1')
```

Logical operands

The *logical_and()*, *logical_invert()*, *logical_or()*, and *logical_xor()* methods expect their arguments to be *logical operands*. A *logical operand* is a *Decimal* instance whose exponent and sign are both zero, and whose digits are all either `0` or `1`.

9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the *getcontext()* and *setcontext()* functions:

decimal.**getcontext**()

Return the current context for the active thread.

decimal.**setcontext**(*c*)

Set the current context for the active thread to *c*.

You can also use the `with` statement and the *localcontext()* function to temporarily change the active context.

decimal.**localcontext**(*ctx=None*, ***kwargs*)

Return a context manager that will set the current context for the active thread to a copy of *ctx* on entry to the with-statement and restore the previous context when exiting the with-statement. If no context is specified, a copy of the current context is used. The *kwargs* argument is used to set the attributes of the new context.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42   # Perform a high precision calculation
    s = calculate_something()
s = +s  # Round the final result back to the default precision
```

Using keyword arguments, the code would be the following:

```
from decimal import localcontext

with localcontext(prec=42) as ctx:
    s = calculate_something()
s = +s
```

Raises *TypeError* if *kwargs* supplies an attribute that *Context* doesn't support. Raises either *TypeError* or *ValueError* if *kwargs* supplies an invalid value for an attribute.

Changed in version 3.11: *localcontext()* now supports setting context attributes through the use of keyword arguments.

New contexts can also be created using the *Context* constructor described below. In addition, the module provides three pre-made contexts:

decimal.**BasicContext**

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to *ROUND_HALF_UP*. All flags are cleared. All traps are enabled (treated as exceptions) except *Inexact*, *Rounded*, and *Subnormal*.

Because many of the traps are enabled, this context is useful for debugging.

decimal.**ExtendedContext**

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to *ROUND_HALF_EVEN*. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of `NaN` or `Infinity` instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

decimal.**DefaultContext**

This context is used by the *Context* constructor as a prototype for new contexts. Changing a field (such a precision) has the effect of changing the default for new contexts created by the *Context* constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are *Context.prec*=`28`, *Context.rounding*=*ROUND_HALF_EVEN*, and enabled traps for *Overflow*, *InvalidOperation*, and *DivisionByZero*.

In addition to the three supplied contexts, new contexts can be created with the *Context* constructor.

class decimal.**Context**(*prec=None*, *rounding=None*, *Emin=None*, *Emax=None*, *capitals=None*, *clamp=None*, *flags=None*, *traps=None*)

Creates a new context. If a field is not specified or is *None*, the default values are copied from the *DefaultContext*. If the *flags* field is not specified or is *None*, all flags are cleared.

prec

An integer in the range [1, *MAX_PREC*] that sets the precision for arithmetic operations in the context.

rounding

One of the constants listed in the section *Rounding Modes*.

traps

flags

Lists of any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

Emin

Emax

Integers specifying the outer limits allowable for exponents. *Emin* must be in the range [*MIN_EMIN*, 0], *Emax* in the range [0, *MAX_EMAX*].

capitals

Either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used: `Decimal('6.02e+23')`.

clamp

Either 0 (the default) or 1. If set to 1, the exponent e of a *Decimal* instance representable in this context is strictly limited to the range `Emin - prec + 1 <= e <= Emax - prec + 1`. If *clamp* is 0 then a weaker condition holds: the adjusted exponent of the *Decimal* instance is at most *Emax*. When *clamp* is 1, a large normal number will, where possible, have its exponent reduced and a corresponding number of zeros added to its coefficient, in order to fit the exponent constraints; this preserves the value of the number but loses information about significant trailing zeros. For example:

```
>>> Context(prec=6, Emax=999, clamp=1).create_decimal('1.23e999')
Decimal('1.23000E+999')
```

A *clamp* value of 1 allows compatibility with the fixed-width decimal interchange formats specified in IEEE 754.

The *Context* class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the *Decimal* methods described above (with the exception of the *adjusted()* and *as_tuple()* methods) there is a corresponding *Context* method. For example, for a *Context* instance C and *Decimal* instance x, `C.exp(x)` is equivalent to `x.exp(context=C)`. Each *Context* method accepts a Python integer (an instance of *int*) anywhere that a Decimal instance is accepted.

clear_flags()

Resets all of the flags to 0.

clear_traps()

Resets all of the traps to 0.

Added in version 3.3.

copy()

Return a duplicate of the context.

copy_decimal(*num*)

Return a copy of the Decimal instance num.

create_decimal(*num*)

Creates a new Decimal instance from *num* but using *self* as context. Unlike the *Decimal* constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace or underscores are permitted.

create_decimal_from_float(*f*)

Creates a new Decimal instance from a float *f* but rounding using *self* as the context. Unlike the *Decimal.from_float()* class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
    ...
decimal.Inexact: None
```

Added in version 3.1.

Etiny()

Returns a value equal to `Emin - prec + 1` which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to *Etiny*.

Etop()

Returns a value equal to `Emax - prec + 1`.

The usual approach to working with decimals is to create *Decimal* instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the *Decimal* class and are only briefly recounted here.

abs(*x*)

Returns the absolute value of *x*.

add(*x*, *y*)

Return the sum of *x* and *y*.

canonical(*x*)

Returns the same Decimal object *x*.

compare(*x*, *y*)

Compares *x* and *y* numerically.

compare_signal(*x*, *y*)

Compares the values of the two operands numerically.

compare_total(*x*, *y*)

Compares two operands using their abstract representation.

compare_total_mag(*x*, *y*)

Compares two operands using their abstract representation, ignoring sign.

copy_abs(*x*)

Returns a copy of *x* with the sign set to 0.

copy_negate(*x*)

Returns a copy of *x* with the sign inverted.

copy_sign(*x*, *y*)

Copies the sign from *y* to *x*.

divide(*x*, *y*)

Return *x* divided by *y*.

divide_int(*x*, *y*)

Return *x* divided by *y*, truncated to an integer.

divmod(*x*, *y*)

Divides two numbers and returns the integer part of the result.

exp(*x*)

Returns `e ** x`.

fma(*x*, *y*, *z*)

Returns *x* multiplied by *y*, plus *z*.

is_canonical(*x*)

Returns `True` if *x* is canonical; otherwise returns `False`.

is_finite(*x*)

Returns `True` if *x* is finite; otherwise returns `False`.

is_infinite(*x*)

Returns `True` if *x* is infinite; otherwise returns `False`.

is_nan(*x*)

Returns `True` if *x* is a qNaN or sNaN; otherwise returns `False`.

is_normal(*x*)

Returns `True` if *x* is a normal number; otherwise returns `False`.

is_qnan(*x*)

Returns `True` if *x* is a quiet NaN; otherwise returns `False`.

is_signed(*x*)

Returns `True` if *x* is negative; otherwise returns `False`.

is_snan(*x*)

Returns `True` if *x* is a signaling NaN; otherwise returns `False`.

is_subnormal(*x*)

Returns `True` if *x* is subnormal; otherwise returns `False`.

is_zero(*x*)

Returns `True` if *x* is a zero; otherwise returns `False`.

ln(*x*)

Returns the natural (base e) logarithm of *x*.

log10(*x*)

Returns the base 10 logarithm of *x*.

logb(*x*)

Returns the exponent of the magnitude of the operand's MSD.

logical_and(*x*, *y*)

Applies the logical operation *and* between each operand's digits.

logical_invert(*x*)

Invert all the digits in *x*.

logical_or(*x*, *y*)

Applies the logical operation *or* between each operand's digits.

logical_xor(*x*, *y*)

Applies the logical operation *xor* between each operand's digits.

max(*x*, *y*)

Compares two values numerically and returns the maximum.

max_mag(*x*, *y*)

Compares the values numerically with their sign ignored.

min(*x*, *y*)

Compares two values numerically and returns the minimum.

min_mag(*x*, *y*)

Compares the values numerically with their sign ignored.

minus(*x*)

Minus corresponds to the unary prefix minus operator in Python.

multiply(*x*, *y*)

Return the product of *x* and *y*.

next_minus(*x*)

Returns the largest representable number smaller than *x*.

next_plus(*x*)

Returns the smallest representable number larger than *x*.

next_toward(*x*, *y*)

Returns the number closest to *x*, in direction towards *y*.

normalize(*x*)

Reduces *x* to its simplest form.

number_class(*x*)

Returns an indication of the class of *x*.

plus(*x*)

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

power(*x*, *y*, *modulo=None*)

Return `x` to the power of `y`, reduced modulo `modulo` if given.

With two arguments, compute `x**y`. If `x` is negative then `y` must be integral. The result will be inexact unless `y` is integral and the result is finite and can be expressed exactly in 'precision' digits. The rounding mode of the context is used. Results are always correctly rounded in the Python version.

`Decimal(0) ** Decimal(0)` results in `InvalidOperation`, and if `InvalidOperation` is not trapped, then results in `Decimal('NaN')`.

Changed in version 3.3: The C module computes *power()* in terms of the correctly rounded *exp()* and *ln()* functions. The result is well-defined but only "almost always correctly rounded".

With three arguments, compute `(x**y) % modulo`. For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- `y` must be nonnegative
- at least one of `x` or `y` must be nonzero
- `modulo` must be nonzero and have at most 'precision' digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing `(x**y) % modulo` with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of `x`, `y` and `modulo`. The result is always exact.

quantize(*x*, *y*)

Returns a value equal to *x* (rounded), having the exponent of *y*.

radix()

Just returns 10, as this is Decimal, :)

remainder(*x*, *y*)

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

remainder_near(*x*, *y*)

Returns `x - y * n`, where *n* is the integer nearest the exact value of `x / y` (if the result is 0 then its sign will be the sign of *x*).

rotate(*x*, *y*)

Returns a rotated copy of *x*, *y* times.

same_quantum(*x*, *y*)

Returns `True` if the two operands have the same exponent.

scaleb(*x*, *y*)

Returns the first operand after adding the second value its exp.

shift(*x*, *y*)

Returns a shifted copy of *x*, *y* times.

sqrt(*x*)

Square root of a non-negative number to context precision.

subtract(*x*, *y*)

Return the difference between *x* and *y*.

to_eng_string(*x*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

to_integral_exact(*x*)

Rounds to an integer.

to_sci_string(*x*)

Converts a number to a string using scientific notation.

9.4.4 Constants

The constants in this section are only relevant for the C module. They are also included in the pure Python version for compatibility.

	32-bit	64-bit
decimal.**MAX_PREC**	425000000	999999999999999999
decimal.**MAX_EMAX**	425000000	999999999999999999
decimal.**MIN_EMIN**	-425000000	-999999999999999999
decimal.**MIN_ETINY**	-849999999	-1999999999999999997

decimal.**HAVE_THREADS**

The value is `True`. Deprecated, because Python now always has threads.

Deprecated since version 3.9.

decimal.**HAVE_CONTEXTVAR**

The default value is `True`. If Python is `configured using the --without-decimal-contextvar option`, the C version uses a thread-local rather than a coroutine-local context and the value is `False`. This is slightly faster in some nested context scenarios.

Added in version 3.8.3.

9.4.5 Rounding modes

decimal.**ROUND_CEILING**

Round towards `Infinity`.

decimal.**ROUND_DOWN**

Round towards zero.

decimal.**ROUND_FLOOR**

Round towards `-Infinity`.

decimal.**ROUND_HALF_DOWN**

Round to nearest with ties going towards zero.

decimal.**ROUND_HALF_EVEN**

Round to nearest with ties going to nearest even integer.

decimal.**ROUND_HALF_UP**

Round to nearest with ties going away from zero.

decimal.**ROUND_UP**

Round away from zero.

decimal.**ROUND_05UP**

Round away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise round towards zero.

9.4.6 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the *DivisionByZero* trap is set, then a *DivisionByZero* exception is raised upon encountering the condition.

class decimal.**Clamped**

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's *Emin* and *Emax* limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

class decimal.**DecimalException**

Base class for other signals and a subclass of *ArithmeticError*.

class decimal.**DivisionByZero**

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns `Infinity` or `-Infinity` with the sign determined by the inputs to the calculation.

class decimal.**Inexact**

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

class decimal.**InvalidOperation**

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns `NaN`. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
Infinity % x
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

class decimal.**Overflow**

Numerical overflow.

Indicates the exponent is larger than *Context.Emax* after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to `Infinity`. In either case, *Inexact* and *Rounded* are also signaled.

class decimal.**Rounded**

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding `5.00` to `5.0`). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

class decimal.**Subnormal**

Exponent was lower than *Emin* prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

class decimal.**Underflow**

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

class decimal.**FloatOperation**

Enable stricter semantics for mixing floats and Decimals.

If the signal is not trapped (default), mixing floats and Decimals is permitted in the *Decimal* constructor, *create_decimal()* and all comparison operators. Both conversion and comparisons are exact. Any occurrence of a mixed operation is silently recorded by setting *FloatOperation* in the context flags. Explicit conversions with *from_float()* or *create_decimal_from_float()* do not set the flag.

Otherwise (the signal is trapped), only equality comparisons and explicit conversions are silent. All other mixed operations raise *FloatOperation*.

The following table summarizes the hierarchy of signals:

```
exceptions.ArithmeticError(exceptions.Exception)
    DecimalException
        Clamped
        DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
        Inexact
            Overflow(Inexact, Rounded)
            Underflow(Inexact, Rounded, Subnormal)
        InvalidOperation
        Rounded
        Subnormal
        FloatOperation(DecimalException, exceptions.TypeError)
```

9.4.7 Floating-point notes

Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent `0.1` exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating-point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.01')
```

(continues on next page)

(continued from previous page)

```
>>> u * (v+w)
Decimal('0.0060000')
```

The *decimal* module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

Special values

The number system for the *decimal* module provides special values including `NaN`, `sNaN`, `-Infinity`, `Infinity`, and two zeros, `+0` and `-0`.

Infinities can be constructed directly with: `Decimal('Infinity')`. Also, they can arise from dividing by zero when the *DivisionByZero* signal is not trapped. Likewise, when the *Overflow* signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return `NaN`, or if the *InvalidOperation* signal is trapped, raise an exception. For example, `0/0` returns `NaN` which means "not a number". This variety of `NaN` is quiet and, once created, will flow through other computations always resulting in another `NaN`. This behavior can be useful for a series of computations that occasionally have missing inputs — it allows the calculation to proceed while flagging specific results as invalid.

A variant is `sNaN` which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python's comparison operators can be a little surprising where a `NaN` is involved. A test for equality where one of the operands is a quiet or signaling `NaN` always returns *False* (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns *True*. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the *InvalidOperation* signal if either operand is a `NaN`, and return *False* if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a `NaN` were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the *compare()* and *compare_signal()* methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating-point representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-1000026')
```

9.4.8 Working with threads

The *getcontext()* function accesses a different *Context* object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the *setcontext()* function automatically assigns its target to the current thread.

If *setcontext()* has not been called before *getcontext()*, then *getcontext()* will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called *DefaultContext*. To control the defaults so that each thread will use the same values throughout the application, directly modify the *DefaultContext* object. This should be done *before* any threads are started so that there won't be a race condition between threads calling *getcontext()*. For example:

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
 . . .
```

9.4.9 Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the *Decimal* class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:     optional grouping separator (comma, period, space, or blank)
    dp:      decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:     optional sign for positive numbers: '+', space or blank
    neg:     optional sign for negative numbers: '-', '(', space or blank
    trailneg:optional trailing minus indicator:  '-', ')', space or blank

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
    >>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
    '1.234.568-'
    >>> moneyfmt(d, curr='$', neg='(', trailneg=')')
    '($1,234,567.89)'
    >>> moneyfmt(Decimal(123456789), sep=' ')
    '123 456 789.00'

9.4.10 Decimal FAQ

Q. It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

A. Some users abbreviate the constructor to just a single letter:

```
>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')
```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

A. The *quantize()* method rounds to a fixed number of decimal places. If the *Inexact* trap is set, it is also useful for validation:

```
>>> TWOPLACES = Decimal(10) ** -2       # same as Decimal('0.01')
```

```
>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')
```

```
>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')
```

```
>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):
   ...
Inexact: None
```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a *quantize()* step:

```
>>> a = Decimal('102.72')           # Initial fixed-point values
>>> b = Decimal('3.17')
>>> a + b                           # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                          # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)     # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)     # And quantize division
Decimal('0.03')
```

In developing fixed-point applications, it is convenient to define functions to handle the *quantize()* step:

```
>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
...
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)
```

```
>>> mul(a, b)                           # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')
```

Q. There are many ways to express the same value. The numbers `200`, `200.000`, `2E2`, and `.02E+4` all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The *`normalize()`* method maps all equivalent values to a single representative:

```
>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]
```

Q. When does rounding occur in a computation?

A. It occurs *after* the computation. The philosophy of the decimal specification is that numbers are considered exact and are created independent of the current context. They can even have greater precision than current context. Computations process with those exact inputs and then rounding (or other context operations) is applied to the *result* of the computation:

```
>>> getcontext().prec = 5
>>> pi = Decimal('3.1415926535')    # More than 5 digits
>>> pi                              # All digits are retained
Decimal('3.1415926535')
>>> pi + 0                          # Rounded after an addition
Decimal('3.1416')
>>> pi - Decimal('0.00005')         # Subtract unrounded numbers, then round
Decimal('3.1415')
>>> pi + 0 - Decimal('0.00005').    # Intermediate values are rounded
Decimal('3.1416')
```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing `5.0E+3` as `5000` keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeroes, losing significance, but keeping the value unchanged:

```
>>> def remove_exponent(d):
...     return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()
```

```
>>> remove_exponent(Decimal('5E+3'))
Decimal('5000')
```

Q. Is there a way to convert a regular float to a *`Decimal`*?

A. Yes, any binary floating-point number can be exactly expressed as a Decimal though an exact conversion may take more precision than intuition would suggest:

```
>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that "what you type is what you get". A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the *Context.create_decimal()* method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

Q. Is the CPython implementation fast for large numbers?

A. Yes. In the CPython and PyPy3 implementations, the C/CFFI versions of the decimal module integrate the high speed libmpdec library for arbitrary precision correctly rounded decimal floating-point arithmetic[1]. `libmpdec` uses Karatsuba multiplication for medium-sized numbers and the Number Theoretic Transform for very large numbers.

The context must be adapted for exact arbitrary precision arithmetic. *Emin* and *Emax* should always be set to the maximum values, *clamp* should always be 0 (the default). Setting *prec* requires some care.

The easiest approach for trying out bignum arithmetic is to use the maximum value for *prec* as well[2]:

```
>>> setcontext(Context(prec=MAX_PREC, Emax=MAX_EMAX, Emin=MIN_EMIN))
>>> x = Decimal(2) ** 256
>>> x / 128
Decimal(
↪'904625697166532776746648320380374280103671755200316906558262375061821325312')
```

For inexact results, *MAX_PREC* is far too large on 64-bit platforms and the available memory will be insufficient:

```
>>> Decimal(1) / 3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
MemoryError
```

On systems with overallocation (e.g. Linux), a more sophisticated approach is to adjust *prec* to the amount of available RAM. Suppose that you have 8GB of RAM and expect 10 simultaneous operands using a maximum of 500MB each:

[1] Added in version 3.3.

[2] Changed in version 3.9: This approach now works for all exact results except for non-integer powers.

```
>>> import sys
>>>
>>> # Maximum number of digits for a single operand using 500MB in 8-byte words
>>> # with 19 digits per word (4-byte and 9 digits for the 32-bit build):
>>> maxdigits = 19 * ((500 * 1024**2) // 8)
>>>
>>> # Check that this works:
>>> c = Context(prec=maxdigits, Emax=MAX_EMAX, Emin=MIN_EMIN)
>>> c.traps[Inexact] = True
>>> setcontext(c)
>>>
>>> # Fill the available precision with nines:
>>> x = Decimal(0).logical_invert() * 9
>>> sys.getsizeof(x)
524288112
>>> x + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  decimal.Inexact: [<class 'decimal.Inexact'>]
```

In general (and especially on systems without overallocation), it is recommended to estimate even tighter bounds and set the *Inexact* trap if all calculations are expected to be exact.

9.5 `fractions` — Rational numbers

Source code: Lib/fractions.py

The *fractions* module provides support for rational number arithmetic.

A Fraction instance can be constructed from a pair of integers, from another rational number, or from a string.

class fractions.**Fraction**(*numerator=0*, *denominator=1*)

class fractions.**Fraction**(*other_fraction*)

class fractions.**Fraction**(*float*)

class fractions.**Fraction**(*decimal*)

class fractions.**Fraction**(*string*)

The first version requires that *numerator* and *denominator* are instances of *numbers.Rational* and returns a new *Fraction* instance with value `numerator/denominator`. If *denominator* is `0`, it raises a *ZeroDivisionError*. The second version requires that *other_fraction* is an instance of *numbers.Rational* and returns a *Fraction* instance with the same value. The next two versions accept either a *float* or a *decimal.Decimal* instance, and return a *Fraction* instance with exactly the same value. Note that due to the usual issues with binary floating point (see tut-fp-issues), the argument to `Fraction(1.1)` is not exactly equal to 11/10, and so `Fraction(1.1)` does *not* return `Fraction(11, 10)` as one might expect. (But see the documentation for the *limit_denominator()* method below.) The last version of the constructor expects a string or unicode instance. The usual form for this instance is:

```
[sign] numerator ['/' denominator]
```

where the optional `sign` may be either '+' or '-' and `numerator` and `denominator` (if present) are strings of decimal digits (underscores may be used to delimit digits as with integral literals in code). In addition, any string that represents a finite value and is accepted by the *float* constructor is also accepted by the *Fraction* constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)
```

The *Fraction* class inherits from the abstract base class *numbers.Rational*, and implements all of the methods and operations from that class. *Fraction* instances are *hashable*, and should be treated as immutable. In addition, *Fraction* has the following properties and methods:

Changed in version 3.2: The *Fraction* constructor now accepts *float* and *decimal.Decimal* instances.

Changed in version 3.9: The *math.gcd()* function is now used to normalize the *numerator* and *denominator*. *math.gcd()* always returns an *int* type. Previously, the GCD type depended on *numerator* and *denominator*.

Changed in version 3.11: Underscores are now permitted when creating a *Fraction* instance from a string, following **PEP 515** rules.

Changed in version 3.11: *Fraction* implements `__int__` now to satisfy `typing.SupportsInt` instance checks.

Changed in version 3.12: Space is allowed around the slash for string inputs: `Fraction('2 / 3')`.

Changed in version 3.12: *Fraction* instances now support float-style formatting, with presentation types `"e"`, `"E"`, `"f"`, `"F"`, `"g"`, `"G"` and `"%"`.

Changed in version 3.13: Formatting of *Fraction* instances without a presentation type now supports fill, alignment, sign handling, minimum width and grouping.

numerator

Numerator of the Fraction in lowest term.

denominator

Denominator of the Fraction in lowest term.

as_integer_ratio()

Return a tuple of two integers, whose ratio is equal to the original Fraction. The ratio is in lowest terms and has a positive denominator.

Added in version 3.8.

is_integer()

Return `True` if the Fraction is an integer.

Added in version 3.12.

classmethod from_float(*flt*)

Alternative constructor which only accepts instances of *float* or *numbers.Integral*. Beware that `Fraction.from_float(0.3)` is not the same value as `Fraction(3, 10)`.

> **Note**
>
> From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *float*.

classmethod from_decimal(*dec*)

Alternative constructor which only accepts instances of *decimal.Decimal* or *numbers.Integral*.

> **Note**
>
> From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *decimal.Decimal* instance.

limit_denominator(*max_denominator=1000000*)

Finds and returns the closest *Fraction* to `self` that has denominator at most max_denominator. This method is useful for finding rational approximations to a given floating-point number:

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)
```

or for recovering a rational number that's represented as a float:

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

__floor__()

Returns the greatest *int* `<= self`. This method can also be accessed through the *math.floor()* function:

```
>>> from math import floor
>>> floor(Fraction(355, 113))
3
```

__ceil__()

Returns the least *int* `>= self`. This method can also be accessed through the *math.ceil()* function.

__round__()

__round__(*ndigits*)

The first version returns the nearest *int* to `self`, rounding half to even. The second version rounds `self` to the nearest multiple of `Fraction(1, 10**ndigits)` (logically, if `ndigits` is negative), again rounding half toward even. This method can also be accessed through the *round()* function.

__format__(*format_spec*, */*)

Provides support for formatting of *Fraction* instances via the *str.format()* method, the *format()* built-in function, or Formatted string literals.

If the `format_spec` format specification string does not end with one of the presentation types `'e'`, `'E'`, `'f'`, `'F'`, `'g'`, `'G'` or `'%'` then formatting follows the general rules for fill, alignment, sign handling, minimum width, and grouping as described in the *format specification mini-language*. The "alternate form" flag `'#'` is supported: if present, it forces the output string to always include an explicit denominator, even when the value being formatted is an exact integer. The zero-fill flag `'0'` is not supported.

If the `format_spec` format specification string ends with one of the presentation types `'e'`, `'E'`, `'f'`, `'F'`, `'g'`, `'G'` or `'%'` then formatting follows the rules outlined for the `float` type in the *Format Specification Mini-Language* section.

Here are some examples:

```
>>> from fractions import Fraction
>>> format(Fraction(103993, 33102), '_')
'103_993/33_102'
>>> format(Fraction(1, 7), '.^+10')
'...+1/7...'
>>> format(Fraction(3, 1), '')
'3'
>>> format(Fraction(3, 1), '#')
'3/1'
>>> format(Fraction(1, 7), '.40g')
'0.1428571428571428571428571428571428571429'
>>> format(Fraction('1234567.855'), '_.2f')
'1_234_567.86'
>>> f"{Fraction(355, 113):*>20.6e}"
'********3.141593e+00'
>>> old_price, new_price = 499, 672
>>> "{:.2%} price increase".format(Fraction(new_price, old_price) - 1)
'34.67% price increase'
```

Module ***numbers***
The abstract base classes making up the numeric tower.

9.6 `random` — Generate pseudo-random numbers

Source code: Lib/random.py

This module implements pseudo-random number generators for various distributions.

For integers, there is uniform selection from a range. For sequences, there is uniform selection of a random element, a function to generate a random permutation of a list in-place, and a function for random sampling without replacement.

On the real line, there are functions to compute uniform, normal (Gaussian), lognormal, negative exponential, gamma, and beta distributions. For generating distributions of angles, the von Mises distribution is available.

Almost all module functions depend on the basic function `random()`, which generates a random float uniformly in the half-open range `0.0 <= X < 1.0`. Python uses the Mersenne Twister as the core generator. It produces 53-bit precision floats and has a period of 2**19937-1. The underlying implementation in C is both fast and threadsafe. The Mersenne Twister is one of the most extensively tested random number generators in existence. However, being completely deterministic, it is not suitable for all purposes, and is completely unsuitable for cryptographic purposes.

The functions supplied by this module are actually bound methods of a hidden instance of the `random.Random` class. You can instantiate your own instances of `Random` to get generators that don't share state.

Class `Random` can also be subclassed if you want to use a different basic generator of your own devising: see the documentation on that class for more details.

The *random* module also provides the *SystemRandom* class which uses the system function *os.urandom()* to generate random numbers from sources provided by the operating system.

Warning

The pseudo-random generators of this module should not be used for security purposes. For security or cryptographic uses, see the *secrets* module.

See also

M. Matsumoto and T. Nishimura, "Mersenne Twister: A 623-dimensionally equidistributed uniform pseudo-random number generator", ACM Transactions on Modeling and Computer Simulation Vol. 8, No. 1, January pp.3–30 1998.

Complementary-Multiply-with-Carry recipe for a compatible alternative random number generator with a long period and comparatively simple update operations.

Note

The global random number generator and instances of *Random* are thread-safe. However, in the free-threaded build, concurrent calls to the global generator or to the same instance of *Random* may encounter contention and poor performance. Consider using separate instances of *Random* per thread instead.

9.6.1 Bookkeeping functions

`random.`**`seed`**`(`*a=None*, *version=2*`)`

Initialize the random number generator.

If *a* is omitted or `None`, the current system time is used. If randomness sources are provided by the operating system, they are used instead of the system time (see the *os.urandom()* function for details on availability).

If *a* is an int, it is used directly.

With version 2 (the default), a *str*, *bytes*, or *bytearray* object gets converted to an *int* and all of its bits are used.

With version 1 (provided for reproducing random sequences from older versions of Python), the algorithm for *str* and *bytes* generates a narrower range of seeds.

Changed in version 3.2: Moved to the version 2 scheme which uses all of the bits in a string seed.

Changed in version 3.11: The *seed* must be one of the following types: `None`, *int*, *float*, *str*, *bytes*, or *bytearray*.

`random.`**`getstate`**`()`

Return an object capturing the current internal state of the generator. This object can be passed to *setstate()* to restore the state.

`random.`**`setstate`**`(`*state*`)`

state should have been obtained from a previous call to *getstate()*, and *setstate()* restores the internal state of the generator to what it was at the time *getstate()* was called.

9.6.2 Functions for bytes

`random.`**`randbytes`**`(`*n*`)`

Generate *n* random bytes.

This method should not be used for generating security tokens. Use *secrets.token_bytes()* instead.

Added in version 3.9.

9.6.3 Functions for integers

random.**randrange**(*stop*)

random.**randrange**(*start*, *stop*[, *step*])

Return a randomly selected element from `range(start, stop, step)`.

This is roughly equivalent to `choice(range(start, stop, step))` but supports arbitrarily large ranges and is optimized for common cases.

The positional argument pattern matches the *range()* function.

Keyword arguments should not be used because they can be interpreted in unexpected ways. For example `randrange(start=100)` is interpreted as `randrange(0, 100, 1)`.

Changed in version 3.2: *randrange()* is more sophisticated about producing equally distributed values. Formerly it used a style like `int(random()*n)` which could produce slightly uneven distributions.

Changed in version 3.12: Automatic conversion of non-integer types is no longer supported. Calls such as `randrange(10.0)` and `randrange(Fraction(10, 1))` now raise a *TypeError*.

random.**randint**(*a*, *b*)

Return a random integer *N* such that `a <= N <= b`. Alias for `randrange(a, b+1)`.

random.**getrandbits**(*k*)

Returns a non-negative Python integer with *k* random bits. This method is supplied with the Mersenne Twister generator and some other generators may also provide it as an optional part of the API. When available, *getrandbits()* enables *randrange()* to handle arbitrarily large ranges.

Changed in version 3.9: This method now accepts zero for *k*.

9.6.4 Functions for sequences

random.**choice**(*seq*)

Return a random element from the non-empty sequence *seq*. If *seq* is empty, raises *IndexError*.

random.**choices**(*population*, *weights=None*, ***, *cum_weights=None*, *k=1*)

Return a *k* sized list of elements chosen from the *population* with replacement. If the *population* is empty, raises *IndexError*.

If a *weights* sequence is specified, selections are made according to the relative weights. Alternatively, if a *cum_weights* sequence is given, the selections are made according to the cumulative weights (perhaps computed using *itertools.accumulate()*). For example, the relative weights `[10, 5, 30, 5]` are equivalent to the cumulative weights `[10, 15, 45, 50]`. Internally, the relative weights are converted to cumulative weights before making selections, so supplying the cumulative weights saves work.

If neither *weights* nor *cum_weights* are specified, selections are made with equal probability. If a weights sequence is supplied, it must be the same length as the *population* sequence. It is a *TypeError* to specify both *weights* and *cum_weights*.

The *weights* or *cum_weights* can use any numeric type that interoperates with the *float* values returned by *random()* (that includes integers, floats, and fractions but excludes decimals). Weights are assumed to be non-negative and finite. A *ValueError* is raised if all weights are zero.

For a given seed, the *choices()* function with equal weighting typically produces a different sequence than repeated calls to *choice()*. The algorithm used by *choices()* uses floating-point arithmetic for internal consistency and speed. The algorithm used by *choice()* defaults to integer arithmetic with repeated selections to avoid small biases from round-off error.

Added in version 3.6.

Changed in version 3.9: Raises a *ValueError* if all weights are zero.

random.**shuffle**(*x*)

Shuffle the sequence *x* in place.

To shuffle an immutable sequence and return a new shuffled list, use `sample(x, k=len(x))` instead.

Note that even for small `len(x)`, the total number of permutations of *x* can quickly grow larger than the period of most random number generators. This implies that most permutations of a long sequence can never be generated. For example, a sequence of length 2080 is the largest that can fit within the period of the Mersenne Twister random number generator.

Changed in version 3.11: Removed the optional parameter *random*.

random.**sample**(*population*, *k*, *, *counts=None*)

Return a *k* length list of unique elements chosen from the population sequence. Used for random sampling without replacement.

Returns a new list containing elements from the population while leaving the original population unchanged. The resulting list is in selection order so that all sub-slices will also be valid random samples. This allows raffle winners (the sample) to be partitioned into grand prize and second place winners (the subslices).

Members of the population need not be *hashable* or unique. If the population contains repeats, then each occurrence is a possible selection in the sample.

Repeated elements can be specified one at a time or with the optional keyword-only *counts* parameter. For example, `sample(['red', 'blue'], counts=[4, 2], k=5)` is equivalent to `sample(['red', 'red', 'red', 'red', 'blue', 'blue'], k=5)`.

To choose a sample from a range of integers, use a *range()* object as an argument. This is especially fast and space efficient for sampling from a large population: `sample(range(10000000), k=60)`.

If the sample size is larger than the population size, a *ValueError* is raised.

Changed in version 3.9: Added the *counts* parameter.

Changed in version 3.11: The *population* must be a sequence. Automatic conversion of sets to lists is no longer supported.

9.6.5 Discrete distributions

The following function generates a discrete distribution.

random.**binomialvariate**(*n=1*, *p=0.5*)

Binomial distribution. Return the number of successes for *n* independent trials with the probability of success in each trial being *p*:

Mathematically equivalent to:

```
sum(random() < p for i in range(n))
```

The number of trials *n* should be a non-negative integer. The probability of success *p* should be between `0.0 <= p <= 1.0`. The result is an integer in the range `0 <= X <= n`.

Added in version 3.12.

9.6.6 Real-valued distributions

The following functions generate specific real-valued distributions. Function parameters are named after the corresponding variables in the distribution's equation, as used in common mathematical practice; most of these equations can be found in any statistics text.

random.**random**()

Return the next random floating-point number in the range `0.0 <= X < 1.0`

random.**uniform**(*a*, *b*)

Return a random floating-point number *N* such that `a <= N <= b` for `a <= b` and `b <= N <= a` for `b < a`.

The end-point value `b` may or may not be included in the range depending on floating-point rounding in the expression `a + (b-a) * random()`.

random.**triangular**(*low*, *high*, *mode*)

Return a random floating-point number *N* such that `low <= N <= high` and with the specified *mode* between those bounds. The *low* and *high* bounds default to zero and one. The *mode* argument defaults to the midpoint between the bounds, giving a symmetric distribution.

random.**betavariate**(*alpha*, *beta*)

Beta distribution. Conditions on the parameters are `alpha > 0` and `beta > 0`. Returned values range between 0 and 1.

random.**expovariate**(*lambd=1.0*)

Exponential distribution. *lambd* is 1.0 divided by the desired mean. It should be nonzero. (The parameter would be called "lambda", but that is a reserved word in Python.) Returned values range from 0 to positive infinity if *lambd* is positive, and from negative infinity to 0 if *lambd* is negative.

Changed in version 3.12: Added the default value for `lambd`.

random.**gammavariate**(*alpha*, *beta*)

Gamma distribution. (*Not* the gamma function!) The shape and scale parameters, *alpha* and *beta*, must have positive values. (Calling conventions vary and some sources define 'beta' as the inverse of the scale).

The probability distribution function is:

```
            x ** (alpha - 1) * math.exp(-x / beta)
pdf(x) =  --------------------------------------
            math.gamma(alpha) * beta ** alpha
```

random.**gauss**(*mu=0.0*, *sigma=1.0*)

Normal distribution, also called the Gaussian distribution. *mu* is the mean, and *sigma* is the standard deviation. This is slightly faster than the *normalvariate()* function defined below.

Multithreading note: When two threads call this function simultaneously, it is possible that they will receive the same return value. This can be avoided in three ways. 1) Have each thread use a different instance of the random number generator. 2) Put locks around all calls. 3) Use the slower, but thread-safe *normalvariate()* function instead.

Changed in version 3.11: *mu* and *sigma* now have default arguments.

random.**lognormvariate**(*mu*, *sigma*)

Log normal distribution. If you take the natural logarithm of this distribution, you'll get a normal distribution with mean *mu* and standard deviation *sigma*. *mu* can have any value, and *sigma* must be greater than zero.

random.**normalvariate**(*mu=0.0*, *sigma=1.0*)

Normal distribution. *mu* is the mean, and *sigma* is the standard deviation.

Changed in version 3.11: *mu* and *sigma* now have default arguments.

random.**vonmisesvariate**(*mu*, *kappa*)

mu is the mean angle, expressed in radians between 0 and 2**pi*, and *kappa* is the concentration parameter, which must be greater than or equal to zero. If *kappa* is equal to zero, this distribution reduces to a uniform random angle over the range 0 to 2**pi*.

random.**paretovariate**(*alpha*)

Pareto distribution. *alpha* is the shape parameter.

random.**weibullvariate**(*alpha*, *beta*)

Weibull distribution. *alpha* is the scale parameter and *beta* is the shape parameter.

9.6.7 Alternative Generator

class random.**Random**([*seed*])

Class that implements the default pseudo-random number generator used by the *random* module.

Changed in version 3.11: Formerly the *seed* could be any hashable object. Now it is limited to: None, *int*, *float*, *str*, *bytes*, or *bytearray*.

Subclasses of Random should override the following methods if they wish to make use of a different basic generator:

seed(*a=None*, *version=2*)

Override this method in subclasses to customise the *seed()* behaviour of Random instances.

getstate()

Override this method in subclasses to customise the *getstate()* behaviour of Random instances.

setstate(*state*)

Override this method in subclasses to customise the *setstate()* behaviour of Random instances.

random()

Override this method in subclasses to customise the *random()* behaviour of Random instances.

Optionally, a custom generator subclass can also supply the following method:

getrandbits(*k*)

Override this method in subclasses to customise the *getrandbits()* behaviour of Random instances.

class random.**SystemRandom**([*seed*])

Class that uses the *os.urandom()* function for generating random numbers from sources provided by the operating system. Not available on all systems. Does not rely on software state, and sequences are not reproducible. Accordingly, the *seed()* method has no effect and is ignored. The *getstate()* and *setstate()* methods raise *NotImplementedError* if called.

9.6.8 Notes on Reproducibility

Sometimes it is useful to be able to reproduce the sequences given by a pseudo-random number generator. By reusing a seed value, the same sequence should be reproducible from run to run as long as multiple threads are not running.

Most of the random module's algorithms and seeding functions are subject to change across Python versions, but two aspects are guaranteed not to change:

- If a new seeding method is added, then a backward compatible seeder will be offered.
- The generator's *random()* method will continue to produce the same sequence when the compatible seeder is given the same seed.

9.6.9 Examples

Basic examples:

```
>>> random()                            # Random float:  0.0 <= x < 1.0
0.37444887175646646

>>> uniform(2.5, 10.0)                  # Random float:  2.5 <= x <= 10.0
3.1800146073117523

>>> expovariate(1 / 5)                  # Interval between arrivals averaging 5␣
↪seconds
5.148957571865031

>>> randrange(10)                       # Integer from 0 to 9 inclusive
```

(continues on next page)

(continued from previous page)

```
7

>>> randrange(0, 101, 2)               # Even integer from 0 to 100 inclusive
26

>>> choice(['win', 'lose', 'draw'])    # Single random element from a sequence
'draw'

>>> deck = 'ace two three four'.split()
>>> shuffle(deck)                      # Shuffle a list
>>> deck
['four', 'two', 'ace', 'three']

>>> sample([10, 20, 30, 40, 50], k=4) # Four samples without replacement
[40, 10, 50, 30]
```

Simulations:

```
>>> # Six roulette wheel spins (weighted sampling with replacement)
>>> choices(['red', 'black', 'green'], [18, 18, 2], k=6)
['red', 'green', 'black', 'black', 'red', 'black']

>>> # Deal 20 cards without replacement from a deck
>>> # of 52 playing cards, and determine the proportion of cards
>>> # with a ten-value:  ten, jack, queen, or king.
>>> deal = sample(['tens', 'low cards'], counts=[16, 36], k=20)
>>> deal.count('tens') / 20
0.15

>>> # Estimate the probability of getting 5 or more heads from 7 spins
>>> # of a biased coin that settles on heads 60% of the time.
>>> sum(binomialvariate(n=7, p=0.6) >= 5 for i in range(10_000)) / 10_000
0.4169

>>> # Probability of the median of 5 samples being in middle two quartiles
>>> def trial():
...     return 2_500 <= sorted(choices(range(10_000), k=5))[2] < 7_500
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.7958
```

Example of statistical bootstrapping using resampling with replacement to estimate a confidence interval for the mean of a sample:

```
# https://www.thoughtco.com/example-of-bootstrapping-3126155
from statistics import fmean as mean
from random import choices

data = [41, 50, 29, 37, 81, 30, 73, 63, 20, 35, 68, 22, 60, 31, 95]
means = sorted(mean(choices(data, k=len(data))) for i in range(100))
print(f'The sample mean of {mean(data):.1f} has a 90% confidence '
      f'interval from {means[5]:.1f} to {means[94]:.1f}')
```

Example of a resampling permutation test to determine the statistical significance or p-value of an observed difference between the effects of a drug versus a placebo:

```
# Example from "Statistics is Easy" by Dennis Shasha and Manda Wilson
from statistics import fmean as mean
from random import shuffle

drug = [54, 73, 53, 70, 73, 68, 52, 65, 65]
placebo = [54, 51, 58, 44, 55, 52, 42, 47, 58, 46]
observed_diff = mean(drug) - mean(placebo)

n = 10_000
count = 0
combined = drug + placebo
for i in range(n):
    shuffle(combined)
    new_diff = mean(combined[:len(drug)]) - mean(combined[len(drug):])
    count += (new_diff >= observed_diff)

print(f'{n} label reshufflings produced only {count} instances with a difference')
print(f'at least as extreme as the observed difference of {observed_diff:.1f}.')
print(f'The one-sided p-value of {count / n:.4f} leads us to reject the null')
print(f'hypothesis that there is no difference between the drug and the placebo.')
```

Simulation of arrival times and service deliveries for a multiserver queue:

```
from heapq import heapify, heapreplace
from random import expovariate, gauss
from statistics import mean, quantiles

average_arrival_interval = 5.6
average_service_time = 15.0
stdev_service_time = 3.5
num_servers = 3

waits = []
arrival_time = 0.0
servers = [0.0] * num_servers  # time when each server becomes available
heapify(servers)
for i in range(1_000_000):
    arrival_time += expovariate(1.0 / average_arrival_interval)
    next_server_available = servers[0]
    wait = max(0.0, next_server_available - arrival_time)
    waits.append(wait)
    service_duration = max(0.0, gauss(average_service_time, stdev_service_time))
    service_completed = arrival_time + wait + service_duration
    heapreplace(servers, service_completed)

print(f'Mean wait: {mean(waits):.1f}   Max wait: {max(waits):.1f}')
print('Quartiles:', [round(q, 1) for q in quantiles(waits)])
```

A Concrete Introduction to Probability (using Python) a tutorial by Peter Norvig covering the basics of probability

theory, how to write simulations, and how to perform data analysis using Python.

9.6.10 Recipes

These recipes show how to efficiently make random selections from the combinatoric iterators in the *itertools* module:

```
def random_product(*args, repeat=1):
    "Random selection from itertools.product(*args, **kwds)"
    pools = [tuple(pool) for pool in args] * repeat
    return tuple(map(random.choice, pools))

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))

def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(range(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Choose r elements with replacement.  Order the result to match the iterable."
    # Result will be in set(itertools.combinations_with_replacement(iterable, r)).
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.choices(range(n), k=r))
    return tuple(pool[i] for i in indices)
```

The default *random()* returns multiples of 2^{-53} in the range $0.0 \le x < 1.0$. All such numbers are evenly spaced and are exactly representable as Python floats. However, many other representable floats in that interval are not possible selections. For example, `0.05954861408025609` isn't an integer multiple of 2^{-53}.

The following recipe takes a different approach. All floats in the interval are possible selections. The mantissa comes from a uniform distribution of integers in the range $2^{52} \le mantissa < 2^{53}$. The exponent comes from a geometric distribution where exponents smaller than *-53* occur half as often as the next larger exponent.

```
from random import Random
from math import ldexp

class FullRandom(Random):

    def random(self):
        mantissa = 0x10_0000_0000_0000 | self.getrandbits(52)
        exponent = -53
        x = 0
        while not x:
            x = self.getrandbits(32)
            exponent += x.bit_length() - 32
        return ldexp(mantissa, exponent)
```

All *real valued distributions* in the class will use the new method:

```
>>> fr = FullRandom()
>>> fr.random()
0.05954861408025609
>>> fr.expovariate(0.25)
8.87925541791544
```

The recipe is conceptually equivalent to an algorithm that chooses from all the multiples of 2^{-1074} in the range $0.0 \le x < 1.0$. All such numbers are evenly spaced, but most have to be rounded down to the nearest representable Python float. (The value 2^{-1074} is the smallest positive unnormalized float and is equal to `math.ulp(0.0)`.)

See also

Generating Pseudo-random Floating-Point Values a paper by Allen B. Downey describing ways to generate more fine-grained floats than normally generated by *random()*.

9.6.11 Command-line usage

Added in version 3.13.

The `random` module can be executed from the command line.

```
python -m random [-h] [-c CHOICE [CHOICE ...] | -i N | -f N] [input ...]
```

The following options are accepted:

-h, --help
: Show the help message and exit.

-c CHOICE [CHOICE ...]
--choice CHOICE [CHOICE ...]
: Print a random choice, using *choice()*.

-i <N>
--integer <N>
: Print a random integer between 1 and N inclusive, using *randint()*.

-f <N>
--float <N>
: Print a random floating-point number between 0 and N inclusive, using *uniform()*.

If no options are given, the output depends on the input:

- String or multiple: same as *--choice*.
- Integer: same as *--integer*.
- Float: same as *--float*.

9.6.12 Command-line example

Here are some examples of the `random` command-line interface:

```
$ # Choose one at random
$ python -m random egg bacon sausage spam "Lobster Thermidor aux crevettes with a␣
↪Mornay sauce"
Lobster Thermidor aux crevettes with a Mornay sauce

$ # Random integer
$ python -m random 6
```

(continues on next page)

(continued from previous page)

```
6

$ # Random floating-point number
$ python -m random 1.8
1.7080016272295635

$ # With explicit arguments
$ python  -m random --choice egg bacon sausage spam "Lobster Thermidor aux␣
↪crevettes with a Mornay sauce"
egg

$ python -m random --integer 6
3

$ python -m random --float 1.8
1.5666339105010318

$ python -m random --integer 6
5

$ python -m random --float 6
3.1942323316565915
```

9.7 `statistics` — Mathematical statistics functions

Added in version 3.4.

Source code: Lib/statistics.py

This module provides functions for calculating mathematical statistics of numeric (*Real*-valued) data.

The module is not intended to be a competitor to third-party libraries such as NumPy, SciPy, or proprietary full-featured statistics packages aimed at professional statisticians such as Minitab, SAS and Matlab. It is aimed at the level of graphing and scientific calculators.

Unless explicitly noted, these functions support *int*, *float*, *Decimal* and *Fraction*. Behaviour with other types (whether in the numeric tower or not) is currently unsupported. Collections with a mix of types are also undefined and implementation-dependent. If your input data consists of mixed types, you may be able to use *map()* to ensure a consistent result, for example: `map(float, input_data)`.

Some datasets use `NaN` (not a number) values to represent missing data. Since NaNs have unusual comparison semantics, they cause surprising or undefined behaviors in the statistics functions that sort data or that count occurrences. The functions affected are `median()`, `median_low()`, `median_high()`, `median_grouped()`, `mode()`, `multimode()`, and `quantiles()`. The `NaN` values should be stripped before calling these functions:

```
>>> from statistics import median
>>> from math import isnan
>>> from itertools import filterfalse

>>> data = [20.7, float('NaN'),19.2, 18.3, float('NaN'), 14.4]
>>> sorted(data)  # This has surprising behavior
[20.7, nan, 14.4, 18.3, 19.2, nan]
>>> median(data)  # This result is unexpected
16.35

>>> sum(map(isnan, data))     # Number of missing values
```

(continues on next page)

(continued from previous page)

```
2
>>> clean = list(filterfalse(isnan, data))  # Strip NaN values
>>> clean
[20.7, 19.2, 18.3, 14.4]
>>> sorted(clean)  # Sorting now works as expected
[14.4, 18.3, 19.2, 20.7]
>>> median(clean)       # This result is now well defined
18.75
```

9.7.1 Averages and measures of central location

These functions calculate an average or typical value from a population or sample.

mean()	Arithmetic mean ("average") of data.
fmean()	Fast, floating-point arithmetic mean, with optional weighting.
geometric_mean()	Geometric mean of data.
harmonic_mean()	Harmonic mean of data.
kde()	Estimate the probability density distribution of the data.
kde_random()	Random sampling from the PDF generated by kde().
median()	Median (middle value) of data.
median_low()	Low median of data.
median_high()	High median of data.
median_grouped()	Median (50th percentile) of grouped data.
mode()	Single mode (most common value) of discrete or nominal data.
multimode()	List of modes (most common values) of discrete or nominal data.
quantiles()	Divide data into intervals with equal probability.

9.7.2 Measures of spread

These functions calculate a measure of how much the population or sample tends to deviate from the typical or average values.

pstdev()	Population standard deviation of data.
pvariance()	Population variance of data.
stdev()	Sample standard deviation of data.
variance()	Sample variance of data.

9.7.3 Statistics for relations between two inputs

These functions calculate statistics regarding relations between two inputs.

covariance()	Sample covariance for two variables.
correlation()	Pearson and Spearman's correlation coefficients.
linear_regression()	Slope and intercept for simple linear regression.

9.7.4 Function details

Note: The functions do not require the data given to them to be sorted. However, for reading convenience, most of the examples show sorted sequences.

`statistics.`**`mean`**`(`*data*`)`

Return the sample arithmetic mean of *data* which can be a sequence or iterable.

The arithmetic mean is the sum of the data divided by the number of data points. It is commonly called "the average", although it is only one of many different mathematical averages. It is a measure of the central location of the data.

If *data* is empty, *StatisticsError* will be raised.

Some examples of use:

```
>>> mean([1, 2, 3, 4, 4])
2.8
>>> mean([-1.0, 2.5, 3.25, 5.75])
2.625

>>> from fractions import Fraction as F
>>> mean([F(3, 7), F(1, 21), F(5, 3), F(1, 3)])
Fraction(13, 21)

>>> from decimal import Decimal as D
>>> mean([D("0.5"), D("0.75"), D("0.625"), D("0.375")])
Decimal('0.5625')
```

Note

The mean is strongly affected by outliers and is not necessarily a typical example of the data points. For a more robust, although less efficient, measure of central tendency, see *median()*.

The sample mean gives an unbiased estimate of the true population mean, so that when taken on average over all the possible samples, `mean(sample)` converges on the true mean of the entire population. If *data* represents the entire population rather than a sample, then `mean(data)` is equivalent to calculating the true population mean μ.

statistics.**fmean**(*data*, *weights=None*)

Convert *data* to floats and compute the arithmetic mean.

This runs faster than the *mean()* function and it always returns a *float*. The *data* may be a sequence or iterable. If the input dataset is empty, raises a *StatisticsError*.

```
>>> fmean([3.5, 4.0, 5.25])
4.25
```

Optional weighting is supported. For example, a professor assigns a grade for a course by weighting quizzes at 20%, homework at 20%, a midterm exam at 30%, and a final exam at 30%:

```
>>> grades = [85, 92, 83, 91]
>>> weights = [0.20, 0.20, 0.30, 0.30]
>>> fmean(grades, weights)
87.6
```

If *weights* is supplied, it must be the same length as the *data* or a *ValueError* will be raised.

Added in version 3.8.

Changed in version 3.11: Added support for *weights*.

statistics.**geometric_mean**(*data*)

Convert *data* to floats and compute the geometric mean.

The geometric mean indicates the central tendency or typical value of the *data* using the product of the values (as opposed to the arithmetic mean which uses their sum).

Raises a *StatisticsError* if the input dataset is empty, if it contains a zero, or if it contains a negative value. The *data* may be a sequence or iterable.

No special efforts are made to achieve exact results. (However, this may change in the future.)

```
>>> round(geometric_mean([54, 24, 36]), 1)
36.0
```

Added in version 3.8.

statistics.**harmonic_mean**(*data*, *weights=None*)

Return the harmonic mean of *data*, a sequence or iterable of real-valued numbers. If *weights* is omitted or None, then equal weighting is assumed.

The harmonic mean is the reciprocal of the arithmetic *mean()* of the reciprocals of the data. For example, the harmonic mean of three values *a*, *b* and *c* will be equivalent to `3/(1/a + 1/b + 1/c)`. If one of the values is zero, the result will be zero.

The harmonic mean is a type of average, a measure of the central location of the data. It is often appropriate when averaging ratios or rates, for example speeds.

Suppose a car travels 10 km at 40 km/hr, then another 10 km at 60 km/hr. What is the average speed?

```
>>> harmonic_mean([40, 60])
48.0
```

Suppose a car travels 40 km/hr for 5 km, and when traffic clears, speeds-up to 60 km/hr for the remaining 30 km of the journey. What is the average speed?

```
>>> harmonic_mean([40, 60], weights=[5, 30])
56.0
```

StatisticsError is raised if *data* is empty, any element is less than zero, or if the weighted sum isn't positive.

The current algorithm has an early-out when it encounters a zero in the input. This means that the subsequent inputs are not tested for validity. (This behavior may change in the future.)

Added in version 3.6.

Changed in version 3.10: Added support for *weights*.

statistics.**kde**(*data*, *h*, *kernel='normal'*, ***, *cumulative=False*)

Kernel Density Estimation (KDE): Create a continuous probability density function or cumulative distribution function from discrete samples.

The basic idea is to smooth the data using a kernel function. to help draw inferences about a population from a sample.

The degree of smoothing is controlled by the scaling parameter *h* which is called the bandwidth. Smaller values emphasize local features while larger values give smoother results.

The *kernel* determines the relative weights of the sample data points. Generally, the choice of kernel shape does not matter as much as the more influential bandwidth smoothing parameter.

Kernels that give some weight to every sample point include *normal* (*gauss*), *logistic*, and *sigmoid*.

Kernels that only give weight to sample points within the bandwidth include *rectangular* (*uniform*), *triangular*, *parabolic* (*epanechnikov*), *quartic* (*biweight*), *triweight*, and *cosine*.

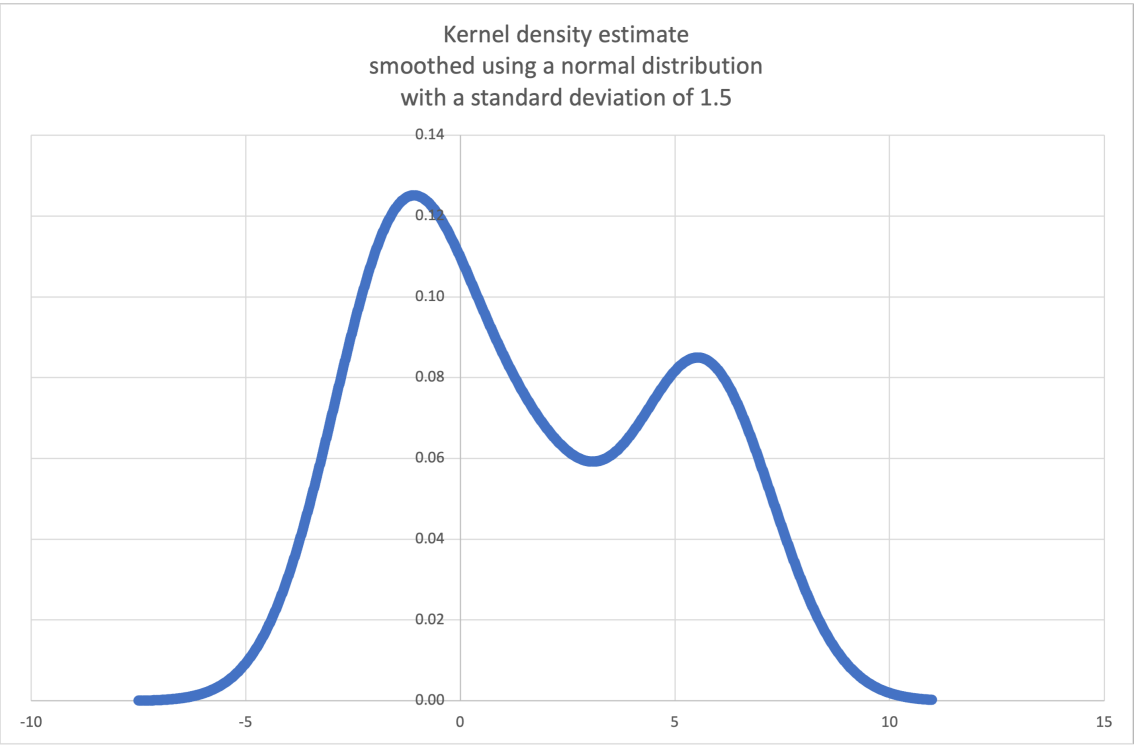
If *cumulative* is true, will return a cumulative distribution function.

A *StatisticsError* will be raised if the *data* sequence is empty.

Wikipedia has an example where we can use *kde()* to generate and plot a probability density function estimated from a small sample:

```
>>> sample = [-2.1, -1.3, -0.4, 1.9, 5.1, 6.2]
>>> f_hat = kde(sample, h=1.5)
>>> xarr = [i/100 for i in range(-750, 1100)]
>>> yarr = [f_hat(x) for x in xarr]
```

The points in `xarr` and `yarr` can be used to make a PDF plot:



Added in version 3.13.

`statistics.`**`kde_random`**(*data*, *h*, *kernel='normal'*, ***, *seed=None*)

Return a function that makes a random selection from the estimated probability density function produced by `kde(data, h, kernel)`.

Providing a *seed* allows reproducible selections. In the future, the values may change slightly as more accurate kernel inverse CDF estimates are implemented. The seed may be an integer, float, str, or bytes.

A *`StatisticsError`* will be raised if the *data* sequence is empty.

Continuing the example for *`kde()`*, we can use *`kde_random()`* to generate new random selections from an estimated probability density function:

```
>>> data = [-2.1, -1.3, -0.4, 1.9, 5.1, 6.2]
>>> rand = kde_random(data, h=1.5, seed=8675309)
>>> new_selections = [rand() for i in range(10)]
>>> [round(x, 1) for x in new_selections]
[0.7, 6.2, 1.2, 6.9, 7.0, 1.8, 2.5, -0.5, -1.8, 5.6]
```

Added in version 3.13.

`statistics.`**`median`**(*data*)

Return the median (middle value) of numeric data, using the common “mean of middle two” method. If *data* is empty, *`StatisticsError`* is raised. *data* can be a sequence or iterable.

The median is a robust measure of central location and is less affected by the presence of outliers. When the number of data points is odd, the middle data point is returned:

```
>>> median([1, 3, 5])
3
```

When the number of data points is even, the median is interpolated by taking the average of the two middle values:

```
>>> median([1, 3, 5, 7])
4.0
```

This is suited for when your data is discrete, and you don't mind that the median may not be an actual data point.

If the data is ordinal (supports order operations) but not numeric (doesn't support addition), consider using *median_low()* or *median_high()* instead.

statistics.**median_low**(*data*)

Return the low median of numeric data. If *data* is empty, *StatisticsError* is raised. *data* can be a sequence or iterable.

The low median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the smaller of the two middle values is returned.

```
>>> median_low([1, 3, 5])
3
>>> median_low([1, 3, 5, 7])
3
```

Use the low median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

statistics.**median_high**(*data*)

Return the high median of data. If *data* is empty, *StatisticsError* is raised. *data* can be a sequence or iterable.

The high median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the larger of the two middle values is returned.

```
>>> median_high([1, 3, 5])
3
>>> median_high([1, 3, 5, 7])
5
```

Use the high median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

statistics.**median_grouped**(*data*, *interval=1.0*)

Estimates the median for numeric data that has been grouped or binned around the midpoints of consecutive, fixed-width intervals.

The *data* can be any iterable of numeric data with each value being exactly the midpoint of a bin. At least one value must be present.

The *interval* is the width of each bin.

For example, demographic information may have been summarized into consecutive ten-year age groups with each group being represented by the 5-year midpoints of the intervals:

```
>>> from collections import Counter
>>> demographics = Counter({
...    25: 172,   # 20 to 30 years old
...    35: 484,   # 30 to 40 years old
```

(continues on next page)

(continued from previous page)

```
...     45: 387,    # 40 to 50 years old
...     55:  22,    # 50 to 60 years old
...     65:   6,    # 60 to 70 years old
... })
...
```

The 50th percentile (median) is the 536th person out of the 1071 member cohort. That person is in the 30 to 40 year old age group.

The regular *median()* function would assume that everyone in the tricenarian age group was exactly 35 years old. A more tenable assumption is that the 484 members of that age group are evenly distributed between 30 and 40. For that, we use *median_grouped()*:

```
>>> data = list(demographics.elements())
>>> median(data)
35
>>> round(median_grouped(data, interval=10), 1)
37.5
```

The caller is responsible for making sure the data points are separated by exact multiples of *interval*. This is essential for getting a correct result. The function does not check this precondition.

Inputs may be any numeric type that can be coerced to a float during the interpolation step.

statistics.**mode**(*data*)

Return the single most common data point from discrete or nominal *data*. The mode (when it exists) is the most typical value and serves as a measure of central location.

If there are multiple modes with the same frequency, returns the first one encountered in the *data*. If the smallest or largest of those is desired instead, use `min(multimode(data))` or `max(multimode(data))`. If the input *data* is empty, *StatisticsError* is raised.

`mode` assumes discrete data and returns a single value. This is the standard treatment of the mode as commonly taught in schools:

```
>>> mode([1, 1, 2, 3, 3, 3, 3, 4])
3
```

The mode is unique in that it is the only statistic in this package that also applies to nominal (non-numeric) data:

```
>>> mode(["red", "blue", "blue", "red", "green", "red", "red"])
'red'
```

Only hashable inputs are supported. To handle type *set*, consider casting to *frozenset*. To handle type *list*, consider casting to *tuple*. For mixed or nested inputs, consider using this slower quadratic algorithm that only depends on equality tests: `max(data, key=data.count)`.

Changed in version 3.8: Now handles multimodal datasets by returning the first mode encountered. Formerly, it raised *StatisticsError* when more than one mode was found.

statistics.**multimode**(*data*)

Return a list of the most frequently occurring values in the order they were first encountered in the *data*. Will return more than one result if there are multiple modes or an empty list if the *data* is empty:

```
>>> multimode('aabbbbccddddeeffffgg')
['b', 'd', 'f']
>>> multimode('')
[]
```

Added in version 3.8.

statistics.**pstdev**(*data*, *mu=None*)

Return the population standard deviation (the square root of the population variance). See *pvariance()* for arguments and other details.

```
>>> pstdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
0.986893273527251
```

statistics.**pvariance**(*data*, *mu=None*)

Return the population variance of *data*, a non-empty sequence or iterable of real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *mu* is given, it should be the *population* mean of the *data*. It can also be used to compute the second moment around a point that is not the mean. If it is missing or `None` (the default), the arithmetic mean is automatically calculated.

Use this function to calculate the variance from the entire population. To estimate the variance from a sample, the *variance()* function is usually a better choice.

Raises *StatisticsError* if *data* is empty.

Examples:

```
>>> data = [0.0, 0.25, 0.25, 1.25, 1.5, 1.75, 2.75, 3.25]
>>> pvariance(data)
1.25
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *mu* to avoid recalculation:

```
>>> mu = mean(data)
>>> pvariance(data, mu)
1.25
```

Decimals and Fractions are supported:

```
>>> from decimal import Decimal as D
>>> pvariance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('24.815')

>>> from fractions import Fraction as F
>>> pvariance([F(1, 4), F(5, 4), F(1, 2)])
Fraction(13, 72)
```

Note

When called with the entire population, this gives the population variance σ^2. When called on a sample instead, this is the biased sample variance s^2, also known as variance with N degrees of freedom.

If you somehow know the true population mean μ, you may use this function to calculate the variance of a sample, giving the known population mean as the second argument. Provided the data points are a random sample of the population, the result will be an unbiased estimate of the population variance.

statistics.**stdev**(*data*, *xbar=None*)

Return the sample standard deviation (the square root of the sample variance). See *variance()* for arguments and other details.

```
>>> stdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
1.0810874155219827
```

statistics.**variance**(*data*, *xbar=None*)

Return the sample variance of *data*, an iterable of at least two real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *xbar* is given, it should be the *sample* mean of *data*. If it is missing or `None` (the default), the mean is automatically calculated.

Use this function when your data is a sample from a population. To calculate the variance from the entire population, see *pvariance()*.

Raises *StatisticsError* if *data* has fewer than two values.

Examples:

```
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> variance(data)
1.3720238095238095
```

If you have already calculated the sample mean of your data, you can pass it as the optional second argument *xbar* to avoid recalculation:

```
>>> m = mean(data)
>>> variance(data, m)
1.3720238095238095
```

This function does not attempt to verify that you have passed the actual mean as *xbar*. Using arbitrary values for *xbar* can lead to invalid or impossible results.

Decimal and Fraction values are supported:

```
>>> from decimal import Decimal as D
>>> variance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('31.01875')

>>> from fractions import Fraction as F
>>> variance([F(1, 6), F(1, 2), F(5, 3)])
Fraction(67, 108)
```

Note

This is the sample variance s^2 with Bessel's correction, also known as variance with N-1 degrees of freedom. Provided that the data points are representative (e.g. independent and identically distributed), the result should be an unbiased estimate of the true population variance.

If you somehow know the actual population mean μ you should pass it to the *pvariance()* function as the *mu* parameter to get the variance of a sample.

statistics.**quantiles**(*data*, ***, *n=4*, *method='exclusive'*)

Divide *data* into *n* continuous intervals with equal probability. Returns a list of `n - 1` cut points separating the intervals.

Set *n* to 4 for quartiles (the default). Set *n* to 10 for deciles. Set *n* to 100 for percentiles which gives the 99 cuts points that separate *data* into 100 equal sized groups. Raises *StatisticsError* if *n* is not least 1.

The *data* can be any iterable containing sample data. For meaningful results, the number of data points in *data* should be larger than *n*. Raises *StatisticsError* if there is not at least one data point.

The cut points are linearly interpolated from the two nearest data points. For example, if a cut point falls one-third of the distance between two sample values, `100` and `112`, the cut-point will evaluate to `104`.

The *method* for computing quantiles can be varied depending on whether the *data* includes or excludes the lowest and highest possible values from the population.

The default *method* is "exclusive" and is used for data sampled from a population that can have more extreme values than found in the samples. The portion of the population falling below the *i-th* of *m* sorted data points is computed as `i / (m + 1)`. Given nine sample values, the method sorts them and assigns the following percentiles: 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%.

Setting the *method* to "inclusive" is used for describing population data or for samples that are known to include the most extreme values from the population. The minimum value in *data* is treated as the 0th percentile and the maximum value is treated as the 100th percentile. The portion of the population falling below the *i-th* of *m* sorted data points is computed as `(i - 1) / (m - 1)`. Given 11 sample values, the method sorts them and assigns the following percentiles: 0%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 100%.

```
# Decile cut points for empirically sampled data
>>> data = [105, 129, 87, 86, 111, 111, 89, 81, 108, 92, 110,
...         100, 75, 105, 103, 109, 76, 119, 99, 91, 103, 129,
...         106, 101, 84, 111, 74, 87, 86, 103, 103, 106, 86,
...         111, 75, 87, 102, 121, 111, 88, 89, 101, 106, 95,
...         103, 107, 101, 81, 109, 104]
>>> [round(q, 1) for q in quantiles(data, n=10)]
[81.0, 86.2, 89.0, 99.4, 102.5, 103.6, 106.0, 109.8, 111.0]
```

Added in version 3.8.

Changed in version 3.13: No longer raises an exception for an input with only a single data point. This allows quantile estimates to be built up one sample point at a time becoming gradually more refined with each new data point.

`statistics.`**`covariance`**(*x*, *y*, */*)

Return the sample covariance of two inputs *x* and *y*. Covariance is a measure of the joint variability of two inputs.

Both inputs must be of the same length (no less than two), otherwise *`StatisticsError`* is raised.

Examples:

```
>>> x = [1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> y = [1, 2, 3, 1, 2, 3, 1, 2, 3]
>>> covariance(x, y)
0.75
>>> z = [9, 8, 7, 6, 5, 4, 3, 2, 1]
>>> covariance(x, z)
-7.5
>>> covariance(z, x)
-7.5
```

Added in version 3.10.

`statistics.`**`correlation`**(*x*, *y*, */*, ***, *method='linear'*)

Return the Pearson's correlation coefficient for two inputs. Pearson's correlation coefficient *r* takes values between -1 and +1. It measures the strength and direction of a linear relationship.

If *method* is "ranked", computes Spearman's rank correlation coefficient for two inputs. The data is replaced by ranks. Ties are averaged so that equal values receive the same rank. The resulting coefficient measures the strength of a monotonic relationship.

Spearman's correlation coefficient is appropriate for ordinal data or for continuous data that doesn't meet the linear proportion requirement for Pearson's correlation coefficient.

Both inputs must be of the same length (no less than two), and need not to be constant, otherwise *`StatisticsError`* is raised.

Example with Kepler's laws of planetary motion:

```
>>> # Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and  Neptune
>>> orbital_period = [88, 225, 365, 687, 4331, 10_756, 30_687, 60_190]    #␣
↪days
>>> dist_from_sun = [58, 108, 150, 228, 778, 1_400, 2_900, 4_500] # million km

>>> # Show that a perfect monotonic relationship exists
>>> correlation(orbital_period, dist_from_sun, method='ranked')
1.0

>>> # Observe that a linear relationship is imperfect
>>> round(correlation(orbital_period, dist_from_sun), 4)
0.9882

>>> # Demonstrate Kepler's third law: There is a linear correlation
>>> # between the square of the orbital period and the cube of the
>>> # distance from the sun.
>>> period_squared = [p * p for p in orbital_period]
>>> dist_cubed = [d * d * d for d in dist_from_sun]
>>> round(correlation(period_squared, dist_cubed), 4)
1.0
```

Added in version 3.10.

Changed in version 3.12: Added support for Spearman's rank correlation coefficient.

statistics.**linear_regression**(*x*, *y*, /, *, *proportional=False*)

Return the slope and intercept of simple linear regression parameters estimated using ordinary least squares. Simple linear regression describes the relationship between an independent variable *x* and a dependent variable *y* in terms of this linear function:

*y = slope * x + intercept + noise*

where `slope` and `intercept` are the regression parameters that are estimated, and `noise` represents the variability of the data that was not explained by the linear regression (it is equal to the difference between predicted and actual values of the dependent variable).

Both inputs must be of the same length (no less than two), and the independent variable *x* cannot be constant; otherwise a *StatisticsError* is raised.

For example, we can use the release dates of the Monty Python films to predict the cumulative number of Monty Python films that would have been produced by 2019 assuming that they had kept the pace.

```
>>> year = [1971, 1975, 1979, 1982, 1983]
>>> films_total = [1, 2, 3, 4, 5]
>>> slope, intercept = linear_regression(year, films_total)
>>> round(slope * 2019 + intercept)
16
```

If *proportional* is true, the independent variable *x* and the dependent variable *y* are assumed to be directly proportional. The data is fit to a line passing through the origin. Since the *intercept* will always be 0.0, the underlying linear function simplifies to:

*y = slope * x + noise*

Continuing the example from *correlation()*, we look to see how well a model based on major planets can predict the orbital distances for dwarf planets:

```
>>> model = linear_regression(period_squared, dist_cubed, proportional=True)
>>> slope = model.slope

>>> # Dwarf planets:   Pluto,  Eris,    Makemake, Haumea, Ceres
```

(continues on next page)

(continued from previous page)

```
>>> orbital_periods = [90_560, 204_199, 111_845, 103_410, 1_680]  # days
>>> predicted_dist = [math.cbrt(slope * (p * p)) for p in orbital_periods]
>>> list(map(round, predicted_dist))
[5912, 10166, 6806, 6459, 414]

>>> [5_906, 10_152, 6_796, 6_450, 414]  # actual distance in million km
[5906, 10152, 6796, 6450, 414]
```

Added in version 3.10.

Changed in version 3.11: Added support for *proportional*.

9.7.5 Exceptions

A single exception is defined:

exception statistics.**StatisticsError**

Subclass of `ValueError` for statistics-related exceptions.

9.7.6 `NormalDist` objects

`NormalDist` is a tool for creating and manipulating normal distributions of a random variable. It is a class that treats the mean and standard deviation of data measurements as a single entity.

Normal distributions arise from the Central Limit Theorem and have a wide range of applications in statistics.

class statistics.**NormalDist**(*mu=0.0*, *sigma=1.0*)

Returns a new *NormalDist* object where *mu* represents the arithmetic mean and *sigma* represents the standard deviation.

If *sigma* is negative, raises `StatisticsError`.

mean

A read-only property for the arithmetic mean of a normal distribution.

median

A read-only property for the median of a normal distribution.

mode

A read-only property for the mode of a normal distribution.

stdev

A read-only property for the standard deviation of a normal distribution.

variance

A read-only property for the variance of a normal distribution. Equal to the square of the standard deviation.

classmethod from_samples(*data*)

Makes a normal distribution instance with *mu* and *sigma* parameters estimated from the *data* using `fmean()` and `stdev()`.

The *data* can be any *iterable* and should consist of values that can be converted to type `float`. If *data* does not contain at least two elements, raises `StatisticsError` because it takes at least one point to estimate a central value and at least two points to estimate dispersion.

samples(*n*, ***, *seed=None*)

Generates *n* random samples for a given mean and standard deviation. Returns a `list` of `float` values.

If *seed* is given, creates a new instance of the underlying random number generator. This is useful for creating reproducible results, even in a multi-threading context.

Changed in version 3.13.

Switched to a faster algorithm. To reproduce samples from previous versions, use *random.seed()* and *random.gauss()*.

pdf(*x*)

Using a probability density function (pdf), compute the relative likelihood that a random variable *X* will be near the given value *x*. Mathematically, it is the limit of the ratio `P(x <= X < x+dx) / dx` as *dx* approaches zero.

The relative likelihood is computed as the probability of a sample occurring in a narrow range divided by the width of the range (hence the word "density"). Since the likelihood is relative to other points, its value can be greater than `1.0`.

cdf(*x*)

Using a cumulative distribution function (cdf), compute the probability that a random variable *X* will be less than or equal to *x*. Mathematically, it is written `P(X <= x)`.

inv_cdf(*p*)

Compute the inverse cumulative distribution function, also known as the quantile function or the percent-point function. Mathematically, it is written `x : P(X <= x) = p`.

Finds the value *x* of the random variable *X* such that the probability of the variable being less than or equal to that value equals the given probability *p*.

overlap(*other*)

Measures the agreement between two normal probability distributions. Returns a value between 0.0 and 1.0 giving the overlapping area for the two probability density functions.

quantiles(*n=4*)

Divide the normal distribution into *n* continuous intervals with equal probability. Returns a list of (n - 1) cut points separating the intervals.

Set *n* to 4 for quartiles (the default). Set *n* to 10 for deciles. Set *n* to 100 for percentiles which gives the 99 cuts points that separate the normal distribution into 100 equal sized groups.

zscore(*x*)

Compute the Standard Score describing *x* in terms of the number of standard deviations above or below the mean of the normal distribution: `(x - mean) / stdev`.

Added in version 3.9.

Instances of *NormalDist* support addition, subtraction, multiplication and division by a constant. These operations are used for translation and scaling. For example:

```
>>> temperature_february = NormalDist(5, 2.5)             # Celsius
>>> temperature_february * (9/5) + 32                     # Fahrenheit
NormalDist(mu=41.0, sigma=4.5)
```

Dividing a constant by an instance of *NormalDist* is not supported because the result wouldn't be normally distributed.

Since normal distributions arise from additive effects of independent variables, it is possible to add and subtract two independent normally distributed random variables represented as instances of *NormalDist*. For example:

```
>>> birth_weights = NormalDist.from_samples([2.5, 3.1, 2.1, 2.4, 2.7, 3.5])
>>> drug_effects = NormalDist(0.4, 0.15)
>>> combined = birth_weights + drug_effects
>>> round(combined.mean, 1)
3.1
>>> round(combined.stdev, 1)
0.5
```

Added in version 3.8.

9.7.7 Examples and Recipes

Classic probability problems

NormalDist readily solves classic probability problems.

For example, given historical data for SAT exams showing that scores are normally distributed with a mean of 1060 and a standard deviation of 195, determine the percentage of students with test scores between 1100 and 1200, after rounding to the nearest whole number:

```
>>> sat = NormalDist(1060, 195)
>>> fraction = sat.cdf(1200 + 0.5) - sat.cdf(1100 - 0.5)
>>> round(fraction * 100.0, 1)
18.4
```

Find the quartiles and deciles for the SAT scores:

```
>>> list(map(round, sat.quantiles()))
[928, 1060, 1192]
>>> list(map(round, sat.quantiles(n=10)))
[810, 896, 958, 1011, 1060, 1109, 1162, 1224, 1310]
```

Monte Carlo inputs for simulations

To estimate the distribution for a model that isn't easy to solve analytically, *NormalDist* can generate input samples for a Monte Carlo simulation:

```
>>> def model(x, y, z):
...     return (3*x + 7*x*y - 5*y) / (11 * z)
...
>>> n = 100_000
>>> X = NormalDist(10, 2.5).samples(n, seed=3652260728)
>>> Y = NormalDist(15, 1.75).samples(n, seed=4582495471)
>>> Z = NormalDist(50, 1.25).samples(n, seed=6582483453)
>>> quantiles(map(model, X, Y, Z))
[1.4591308524824727, 1.8035946855390597, 2.175091447274739]
```

Approximating binomial distributions

Normal distributions can be used to approximate Binomial distributions when the sample size is large and when the probability of a successful trial is near 50%.

For example, an open source conference has 750 attendees and two rooms with a 500 person capacity. There is a talk about Python and another about Ruby. In previous conferences, 65% of the attendees preferred to listen to Python talks. Assuming the population preferences haven't changed, what is the probability that the Python room will stay within its capacity limits?

```
>>> n = 750             # Sample size
>>> p = 0.65            # Preference for Python
>>> q = 1.0 - p         # Preference for Ruby
>>> k = 500             # Room capacity

>>> # Approximation using the cumulative normal distribution
>>> from math import sqrt
>>> round(NormalDist(mu=n*p, sigma=sqrt(n*p*q)).cdf(k + 0.5), 4)
0.8402
```

(continues on next page)

(continued from previous page)

```
>>> # Exact solution using the cumulative binomial distribution
>>> from math import comb, fsum
>>> round(fsum(comb(n, r) * p**r * q**(n-r) for r in range(k+1)), 4)
0.8402

>>> # Approximation using a simulation
>>> from random import seed, binomialvariate
>>> seed(8675309)
>>> mean(binomialvariate(n, p) <= k for i in range(10_000))
0.8406
```

Naive bayesian classifier

Normal distributions commonly arise in machine learning problems.

Wikipedia has a nice example of a Naive Bayesian Classifier. The challenge is to predict a person's gender from measurements of normally distributed features including height, weight, and foot size.

We're given a training dataset with measurements for eight people. The measurements are assumed to be normally distributed, so we summarize the data with *NormalDist*:

```
>>> height_male = NormalDist.from_samples([6, 5.92, 5.58, 5.92])
>>> height_female = NormalDist.from_samples([5, 5.5, 5.42, 5.75])
>>> weight_male = NormalDist.from_samples([180, 190, 170, 165])
>>> weight_female = NormalDist.from_samples([100, 150, 130, 150])
>>> foot_size_male = NormalDist.from_samples([12, 11, 12, 10])
>>> foot_size_female = NormalDist.from_samples([6, 8, 7, 9])
```

Next, we encounter a new person whose feature measurements are known but whose gender is unknown:

```
>>> ht = 6.0        # height
>>> wt = 130        # weight
>>> fs = 8          # foot size
```

Starting with a 50% prior probability of being male or female, we compute the posterior as the prior times the product of likelihoods for the feature measurements given the gender:

```
>>> prior_male = 0.5
>>> prior_female = 0.5
>>> posterior_male = (prior_male * height_male.pdf(ht) *
...                   weight_male.pdf(wt) * foot_size_male.pdf(fs))

>>> posterior_female = (prior_female * height_female.pdf(ht) *
...                     weight_female.pdf(wt) * foot_size_female.pdf(fs))
```

The final prediction goes to the largest posterior. This is known as the maximum a posteriori or MAP:

```
>>> 'male' if posterior_male > posterior_female else 'female'
'female'
```

CHAPTER

TEN

FUNCTIONAL PROGRAMMING MODULES

The modules described in this chapter provide functions and classes that support a functional programming style, and general operations on callables.

The following modules are documented in this chapter:

10.1 `itertools` — Functions creating iterators for efficient looping

This module implements a number of *iterator* building blocks inspired by constructs from APL, Haskell, and SML. Each has been recast in a form suitable for Python.

The module standardizes a core set of fast, memory efficient tools that are useful by themselves or in combination. Together, they form an "iterator algebra" making it possible to construct specialized tools succinctly and efficiently in pure Python.

For instance, SML provides a tabulation tool: `tabulate(f)` which produces a sequence `f(0), f(1), ...`. The same effect can be achieved in Python by combining *`map()`* and *`count()`* to form `map(f, count())`.

Infinite iterators:

Iterator	Arguments	Results	Example
`count()`	[start[, step]]	start, start+step, start+2*step, …	`count(10) → 10 11 12 13 14 ...`
`cycle()`	p	p0, p1, … plast, p0, p1, …	`cycle('ABCD') → A B C D A B C D ...`
`repeat()`	elem [,n]	elem, elem, elem, … endlessly or up to n times	`repeat(10, 3) → 10 10 10`

Iterators terminating on the shortest input sequence:

Iterator	Arguments	Results	Example
accumulate()	p [,func]	p0, p0+p1, p0+p1+p2, …	`accumulate([1,2,3,4,5]) → 1 3 6 10 15`
batched()	p, n	(p0, p1, …, p_n-1), …	`batched('ABCDEFG', n=3) → ABC DEF G`
chain()	p, q, …	p0, p1, … plast, q0, q1, …	`chain('ABC', 'DEF') → A B C D E F`
chain.from_iterable	iterable	p0, p1, … plast, q0, q1, …	`chain.from_iterable(['ABC', 'DEF']) → A B C D E F`
compress()	data, selectors	(d[0] if s[0]), (d[1] if s[1]), …	`compress('ABCDEF', [1,0,1,0,1,1]) → A C E F`
dropwhile()	predicate, seq	seq[n], seq[n+1], starting when predicate fails	`dropwhile(lambda x: x<5, [1,4,6,3,8]) → 6 3 8`
filterfalse()	predicate, seq	elements of seq where predicate(elem) fails	`filterfalse(lambda x: x<5, [1,4,6,3,8]) → 6 8`
groupby()	iterable[, key]	sub-iterators grouped by value of key(v)	`groupby(['A','B','DEF'], len) → (1, A B) (3, DEF)`
islice()	seq, [start,] stop [, step]	elements from seq[start:stop:step]	`islice('ABCDEFG', 2, None) → C D E F G`
pairwise()	iterable	(p[0], p[1]), (p[1], p[2])	`pairwise('ABCDEFG') → AB BC CD DE EF FG`
starmap()	func, seq	func(*seq[0]), func(*seq[1]), …	`starmap(pow, [(2,5), (3,2), (10,3)]) → 32 9 1000`
takewhile()	predicate, seq	seq[0], seq[1], until predicate fails	`takewhile(lambda x: x<5, [1,4,6,3,8]) → 1 4`
tee()	it, n	it1, it2, … itn splits one iterator into n	
zip_longest()	p, q, …	(p[0], q[0]), (p[1], q[1]), …	`zip_longest('ABCD', 'xy', fillvalue='-') → Ax By C- D-`

Combinatoric iterators:

Iterator	Arguments	Results
product()	p, q, … [repeat=1]	cartesian product, equivalent to a nested for-loop
permutations()	p[, r]	r-length tuples, all possible orderings, no repeated elements
combinations()	p, r	r-length tuples, in sorted order, no repeated elements
combinations_with_replacement()	p, r	r-length tuples, in sorted order, with repeated elements

Examples	Results
`product('ABCD', repeat=2)`	`AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD`
`permutations('ABCD', 2)`	`AB AC AD BA BC BD CA CB CD DA DB DC`
`combinations('ABCD', 2)`	`AB AC AD BC BD CD`
`combinations_with_replacement('ABCD', 2)`	`AA AB AC AD BB BC BD CC CD DD`

10.1.1 Itertool Functions

The following functions all construct and return iterators. Some provide streams of infinite length, so they should only be accessed by functions or loops that truncate the stream.

itertools.**accumulate**(*iterable*[, *function*, *, *initial=None*])

Make an iterator that returns accumulated sums or accumulated results from other binary functions.

The *function* defaults to addition. The *function* should accept two arguments, an accumulated total and a value from the *iterable*.

If an *initial* value is provided, the accumulation will start with that value and the output will have one more element than the input iterable.

Roughly equivalent to:

```
def accumulate(iterable, function=operator.add, *, initial=None):
    'Return running totals'
    # accumulate([1,2,3,4,5]) → 1 3 6 10 15
    # accumulate([1,2,3,4,5], initial=100) → 100 101 103 106 110 115
    # accumulate([1,2,3,4,5], operator.mul) → 1 2 6 24 120

    iterator = iter(iterable)
    total = initial
    if initial is None:
        try:
            total = next(iterator)
        except StopIteration:
            return

    yield total
    for element in iterator:
        total = function(total, element)
        yield total
```

To compute a running minimum, set *function* to `min()`. For a running maximum, set *function* to `max()`. Or for a running product, set *function* to `operator.mul()`. To build an amortization table, accumulate the interest and apply payments:

```
>>> data = [3, 4, 6, 2, 1, 9, 0, 7, 5, 8]
>>> list(accumulate(data, max))                # running maximum
[3, 4, 6, 6, 6, 9, 9, 9, 9, 9]
>>> list(accumulate(data, operator.mul))       # running product
[3, 12, 72, 144, 144, 1296, 0, 0, 0, 0]

# Amortize a 5% loan of 1000 with 10 annual payments of 90
>>> update = lambda balance, payment: round(balance * 1.05) - payment
>>> list(accumulate(repeat(90, 10), update, initial=1_000))
[1000, 960, 918, 874, 828, 779, 728, 674, 618, 559, 497]
```

See `functools.reduce()` for a similar function that returns only the final accumulated value.

Added in version 3.2.

Changed in version 3.3: Added the optional *function* parameter.

Changed in version 3.8: Added the optional *initial* parameter.

itertools.**batched**(*iterable*, *n*, *, *strict=False*)

Batch data from the *iterable* into tuples of length *n*. The last batch may be shorter than *n*.

If *strict* is true, will raise a `ValueError` if the final batch is shorter than *n*.

Loops over the input iterable and accumulates data into tuples up to size *n*. The input is consumed lazily, just enough to fill a batch. The result is yielded as soon as the batch is full or when the input iterable is exhausted:

```
>>> flattened_data = ['roses', 'red', 'violets', 'blue', 'sugar', 'sweet']
>>> unflattened = list(batched(flattened_data, 2))
>>> unflattened
[('roses', 'red'), ('violets', 'blue'), ('sugar', 'sweet')]
```

Roughly equivalent to:

```
def batched(iterable, n, *, strict=False):
    # batched('ABCDEFG', 3) → ABC DEF G
    if n < 1:
        raise ValueError('n must be at least one')
    iterator = iter(iterable)
    while batch := tuple(islice(iterator, n)):
        if strict and len(batch) != n:
            raise ValueError('batched(): incomplete batch')
        yield batch
```

Added in version 3.12.

Changed in version 3.13: Added the *strict* option.

itertools.**chain**(**iterables*)

Make an iterator that returns elements from the first iterable until it is exhausted, then proceeds to the next iterable, until all of the iterables are exhausted. This combines multiple data sources into a single iterator. Roughly equivalent to:

```
def chain(*iterables):
    # chain('ABC', 'DEF') → A B C D E F
    for iterable in iterables:
        yield from iterable
```

classmethod chain.**from_iterable**(*iterable*)

Alternate constructor for `chain()`. Gets chained inputs from a single iterable argument that is evaluated lazily. Roughly equivalent to:

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) → A B C D E F
    for iterable in iterables:
        yield from iterable
```

itertools.**combinations**(*iterable*, *r*)

Return *r* length subsequences of elements from the input *iterable*.

The output is a subsequence of `product()` keeping only entries that are subsequences of the *iterable*. The length of the output is given by `math.comb()` which computes `n! / r! / (n - r)!` when `0 ≤ r ≤ n` or zero when `r > n`.

The combination tuples are emitted in lexicographic order according to the order of the input *iterable*. If the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. If the input elements are unique, there will be no repeated values within each combination.

Roughly equivalent to:

```
def combinations(iterable, r):
    # combinations('ABCD', 2) → AB AC AD BC BD CD
    # combinations(range(4), 3) → 012 013 023 123
```

(continues on next page)

(continued from previous page)

```
    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
    indices = list(range(r))

    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != i + n - r:
                break
        else:
            return
        indices[i] += 1
        for j in range(i+1, r):
            indices[j] = indices[j-1] + 1
        yield tuple(pool[i] for i in indices)
```

itertools.**combinations_with_replacement**(*iterable*, *r*)

Return *r* length subsequences of elements from the input *iterable* allowing individual elements to be repeated more than once.

The output is a subsequence of *product()* that keeps only entries that are subsequences (with possible repeated elements) of the *iterable*. The number of subsequence returned is `(n + r - 1)! / r! / (n - 1)!` when `n > 0`.

The combination tuples are emitted in lexicographic order according to the order of the input *iterable*. if the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. If the input elements are unique, the generated combinations will also be unique.

Roughly equivalent to:

```
def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) → AA AB AC BB BC CC

    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r

    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i:] = [indices[i] + 1] * (r - i)
        yield tuple(pool[i] for i in indices)
```

Added in version 3.1.

itertools.**compress**(*data*, *selectors*)

Make an iterator that returns elements from *data* where the corresponding element in *selectors* is true. Stops when either the *data* or *selectors* iterables have been exhausted. Roughly equivalent to:

```
def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) → A C E F
    return (datum for datum, selector in zip(data, selectors) if selector)
```

Added in version 3.1.

itertools.**count**(*start=0*, *step=1*)

Make an iterator that returns evenly spaced values beginning with *start*. Can be used with `map()` to generate consecutive data points or with `zip()` to add sequence numbers. Roughly equivalent to:

```
def count(start=0, step=1):
    # count(10) → 10 11 12 13 14 ...
    # count(2.5, 0.5) → 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

When counting with floating-point numbers, better accuracy can sometimes be achieved by substituting multiplicative code such as: `(start + step * i for i in count())`.

Changed in version 3.1: Added *step* argument and allowed non-integer arguments.

itertools.**cycle**(*iterable*)

Make an iterator returning elements from the *iterable* and saving a copy of each. When the iterable is exhausted, return elements from the saved copy. Repeats indefinitely. Roughly equivalent to:

```
def cycle(iterable):
    # cycle('ABCD') → A B C D A B C D A B C D ...

    saved = []
    for element in iterable:
        yield element
        saved.append(element)

    while saved:
        for element in saved:
            yield element
```

This itertool may require significant auxiliary storage (depending on the length of the iterable).

itertools.**dropwhile**(*predicate*, *iterable*)

Make an iterator that drops elements from the *iterable* while the *predicate* is true and afterwards returns every element. Roughly equivalent to:

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,3,8]) → 6 3 8

    iterator = iter(iterable)
    for x in iterator:
        if not predicate(x):
            yield x
            break

    for x in iterator:
        yield x
```

Note this does not produce *any* output until the predicate first becomes false, so this itertool may have a lengthy start-up time.

itertools.**filterfalse**(*predicate*, *iterable*)

Make an iterator that filters elements from the *iterable* returning only those for which the *predicate* returns a false value. If *predicate* is `None`, returns the items that are false. Roughly equivalent to:

```
def filterfalse(predicate, iterable):
    # filterfalse(lambda x: x<5, [1,4,6,3,8]) → 6 8

    if predicate is None:
        predicate = bool

    for x in iterable:
        if not predicate(x):
            yield x
```

itertools.**groupby**(*iterable*, *key=None*)

Make an iterator that returns consecutive keys and groups from the *iterable*. The *key* is a function computing a key value for each element. If not specified or is `None`, *key* defaults to an identity function and returns the element unchanged. Generally, the iterable needs to already be sorted on the same key function.

The operation of *groupby()* is similar to the `uniq` filter in Unix. It generates a break or new group every time the value of the key function changes (which is why it is usually necessary to have sorted the data using the same key function). That behavior differs from SQL's GROUP BY which aggregates common elements regardless of their input order.

The returned group is itself an iterator that shares the underlying iterable with *groupby()*. Because the source is shared, when the *groupby()* object is advanced, the previous group is no longer visible. So, if that data is needed later, it should be stored as a list:

```
groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)
```

groupby() is roughly equivalent to:

```
def groupby(iterable, key=None):
    # [k for k, g in groupby('AAAABBBCCDAABBB')] → A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] → AAAA BBB CC D

    keyfunc = (lambda x: x) if key is None else key
    iterator = iter(iterable)
    exhausted = False

    def _grouper(target_key):
        nonlocal curr_value, curr_key, exhausted
        yield curr_value
        for curr_value in iterator:
            curr_key = keyfunc(curr_value)
            if curr_key != target_key:
                return
            yield curr_value
        exhausted = True

    try:
        curr_value = next(iterator)
    except StopIteration:
        return
```

(continues on next page)

(continued from previous page)

```
    curr_key = keyfunc(curr_value)

    while not exhausted:
        target_key = curr_key
        curr_group = _grouper(target_key)
        yield curr_key, curr_group
        if curr_key == target_key:
            for _ in curr_group:
                pass
```

itertools.**islice**(*iterable*, *stop*)

itertools.**islice**(*iterable*, *start*, *stop*[, *step*])

Make an iterator that returns selected elements from the iterable. Works like sequence slicing but does not support negative values for *start*, *stop*, or *step*.

If *start* is zero or `None`, iteration starts at zero. Otherwise, elements from the iterable are skipped until *start* is reached.

If *stop* is `None`, iteration continues until the input is exhausted, if at all. Otherwise, it stops at the specified position.

If *step* is `None`, the step defaults to one. Elements are returned consecutively unless *step* is set higher than one which results in items being skipped.

Roughly equivalent to:

```
def islice(iterable, *args):
    # islice('ABCDEFG', 2) → A B
    # islice('ABCDEFG', 2, 4) → C D
    # islice('ABCDEFG', 2, None) → C D E F G
    # islice('ABCDEFG', 0, None, 2) → A C E G

    s = slice(*args)
    start = 0 if s.start is None else s.start
    stop = s.stop
    step = 1 if s.step is None else s.step
    if start < 0 or (stop is not None and stop < 0) or step <= 0:
        raise ValueError

    indices = count() if stop is None else range(max(start, stop))
    next_i = start
    for i, element in zip(indices, iterable):
        if i == next_i:
            yield element
            next_i += step
```

If the input is an iterator, then fully consuming the *islice* advances the input iterator by `max(start, stop)` steps regardless of the *step* value.

itertools.**pairwise**(*iterable*)

Return successive overlapping pairs taken from the input *iterable*.

The number of 2-tuples in the output iterator will be one fewer than the number of inputs. It will be empty if the input iterable has fewer than two values.

Roughly equivalent to:

```
def pairwise(iterable):
    # pairwise('ABCDEFG') → AB BC CD DE EF FG
```

(continues on next page)

(continued from previous page)

```
    iterator = iter(iterable)
    a = next(iterator, None)

    for b in iterator:
        yield a, b
        a = b
```

Added in version 3.10.

itertools.**permutations**(*iterable*, *r=None*)

Return successive *r* length permutations of elements from the *iterable*.

If *r* is not specified or is `None`, then *r* defaults to the length of the *iterable* and all possible full-length permutations are generated.

The output is a subsequence of *`product()`* where entries with repeated elements have been filtered out. The length of the output is given by *`math.perm()`* which computes `n! / (n - r)!` when `0 ≤ r ≤ n` or zero when `r > n`.

The permutation tuples are emitted in lexicographic order according to the order of the input *iterable*. If the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. If the input elements are unique, there will be no repeated values within a permutation.

Roughly equivalent to:

```
def permutations(iterable, r=None):
    # permutations('ABCD', 2) → AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) → 012 021 102 120 201 210

    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return

    indices = list(range(n))
    cycles = list(range(n, n-r, -1))
    yield tuple(pool[i] for i in indices[:r])

    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[i:i+1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        else:
            return
```

itertools.**product**(**iterables*, *repeat=1*)

Cartesian product of the input iterables.

Roughly equivalent to nested for-loops in a generator expression. For example, `product(A, B)` returns the same as `((x,y) for x in A for y in B)`.

The nested loops cycle like an odometer with the rightmost element advancing on every iteration. This pattern creates a lexicographic ordering so that if the input's iterables are sorted, the product tuples are emitted in sorted order.

To compute the product of an iterable with itself, specify the number of repetitions with the optional *repeat* keyword argument. For example, `product(A, repeat=4)` means the same as `product(A, A, A, A)`.

This function is roughly equivalent to the following code, except that the actual implementation does not build up intermediate results in memory:

```
def product(*iterables, repeat=1):
    # product('ABCD', 'xy') → Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) → 000 001 010 011 100 101 110 111

    if repeat < 0:
        raise ValueError('repeat argument cannot be negative')
    pools = [tuple(pool) for pool in iterables] * repeat

    result = [[]]
    for pool in pools:
        result = [x+[y] for x in result for y in pool]

    for prod in result:
        yield tuple(prod)
```

Before *product()* runs, it completely consumes the input iterables, keeping pools of values in memory to generate the products. Accordingly, it is only useful with finite inputs.

`itertools.`**`repeat`**(*object*[, *times*])

Make an iterator that returns *object* over and over again. Runs indefinitely unless the *times* argument is specified.

Roughly equivalent to:

```
def repeat(object, times=None):
    # repeat(10, 3) → 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in range(times):
            yield object
```

A common use for *repeat* is to supply a stream of constant values to *map* or *zip*:

```
>>> list(map(pow, range(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

`itertools.`**`starmap`**(*function*, *iterable*)

Make an iterator that computes the *function* using arguments obtained from the *iterable*. Used instead of *map()* when argument parameters have already been "pre-zipped" into tuples.

The difference between *map()* and *starmap()* parallels the distinction between `function(a,b)` and `function(*c)`. Roughly equivalent to:

```
def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) → 32 9 1000
    for args in iterable:
        yield function(*args)
```

itertools.**takewhile**(*predicate*, *iterable*)

Make an iterator that returns elements from the *iterable* as long as the *predicate* is true. Roughly equivalent to:

```
def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,3,8]) → 1 4
    for x in iterable:
        if not predicate(x):
            break
        yield x
```

Note, the element that first fails the predicate condition is consumed from the input iterator and there is no way to access it. This could be an issue if an application wants to further consume the input iterator after *takewhile* has been run to exhaustion. To work around this problem, consider using more-itertools before_and_after() instead.

itertools.**tee**(*iterable*, *n=2*)

Return *n* independent iterators from a single iterable.

Roughly equivalent to:

```
def tee(iterable, n=2):
    if n < 0:
        raise ValueError
    if n == 0:
        return ()
    iterator = _tee(iterable)
    result = [iterator]
    for _ in range(n - 1):
        result.append(_tee(iterator))
    return tuple(result)

class _tee:

    def __init__(self, iterable):
        it = iter(iterable)
        if isinstance(it, _tee):
            self.iterator = it.iterator
            self.link = it.link
        else:
            self.iterator = it
            self.link = [None, None]

    def __iter__(self):
        return self

    def __next__(self):
        link = self.link
        if link[1] is None:
            link[0] = next(self.iterator)
            link[1] = [None, None]
        value, self.link = link
        return value
```

When the input *iterable* is already a tee iterator object, all members of the return tuple are constructed as if they had been produced by the upstream `tee()` call. This "flattening step" allows nested `tee()` calls to share the same underlying data chain and to have a single update step rather than a chain of calls.

The flattening property makes tee iterators efficiently peekable:

```
def lookahead(tee_iterator):
     "Return the next value without moving the input forward"
     [forked_iterator] = tee(tee_iterator, 1)
     return next(forked_iterator)
```

```
>>> iterator = iter('abcdef')
>>> [iterator] = tee(iterator, 1)    # Make the input peekable
>>> next(iterator)                   # Move the iterator forward
'a'
>>> lookahead(iterator)              # Check next value
'b'
>>> next(iterator)                   # Continue moving forward
'b'
```

`tee` iterators are not threadsafe. A *RuntimeError* may be raised when simultaneously using iterators returned by the same *tee()* call, even if the original *iterable* is threadsafe.

This itertool may require significant auxiliary storage (depending on how much temporary data needs to be stored). In general, if one iterator uses most or all of the data before another iterator starts, it is faster to use *list()* instead of *tee()*.

itertools.**zip_longest**(**iterables*, *fillvalue=None*)

Make an iterator that aggregates elements from each of the *iterables*.

If the iterables are of uneven length, missing values are filled-in with *fillvalue*. If not specified, *fillvalue* defaults to `None`.

Iteration continues until the longest iterable is exhausted.

Roughly equivalent to:

```
def zip_longest(*iterables, fillvalue=None):
    # zip_longest('ABCD', 'xy', fillvalue='-') → Ax By C- D-

    iterators = list(map(iter, iterables))
    num_active = len(iterators)
    if not num_active:
        return

    while True:
        values = []
        for i, iterator in enumerate(iterators):
            try:
                value = next(iterator)
            except StopIteration:
                num_active -= 1
                if not num_active:
                    return
                iterators[i] = repeat(fillvalue)
                value = fillvalue
            values.append(value)
        yield tuple(values)
```

If one of the iterables is potentially infinite, then the *zip_longest()* function should be wrapped with something that limits the number of calls (for example *islice()* or *takewhile()*).

10.1.2 Itertools Recipes

This section shows recipes for creating an extended toolset using the existing itertools as building blocks.

The primary purpose of the itertools recipes is educational. The recipes show various ways of thinking about individual tools — for example, that `chain.from_iterable` is related to the concept of flattening. The recipes also give ideas about ways that the tools can be combined — for example, how `starmap()` and `repeat()` can work together. The recipes also show patterns for using itertools with the *`operator`* and *`collections`* modules as well as with the built-in itertools such as `map()`, `filter()`, `reversed()`, and `enumerate()`.

A secondary purpose of the recipes is to serve as an incubator. The `accumulate()`, `compress()`, and `pairwise()` itertools started out as recipes. Currently, the `sliding_window()`, `iter_index()`, and `sieve()` recipes are being tested to see whether they prove their worth.

Substantially all of these recipes and many, many others can be installed from the more-itertools project found on the Python Package Index:

```
python -m pip install more-itertools
```

Many of the recipes offer the same high performance as the underlying toolset. Superior memory performance is kept by processing elements one at a time rather than bringing the whole iterable into memory all at once. Code volume is kept small by linking the tools together in a functional style. High speed is retained by preferring "vectorized" building blocks over the use of for-loops and *generators* which incur interpreter overhead.

```
from collections import Counter, deque
from contextlib import suppress
from functools import reduce
from math import comb, prod, sumprod, isqrt
from operator import itemgetter, getitem, mul, neg

def take(n, iterable):
    "Return first n items of the iterable as a list."

```

10.2 `functools` — Higher-order functions and operations on callable objects

Source code: Lib/functools.py

The *functools* module is for higher-order functions: functions that act on or return other functions. In general, any callable object can be treated as a function for the purposes of this module.

The *functools* module defines the following functions:

`@functools.cache`(*user_function*)

Simple lightweight unbounded function cache. Sometimes called "memoize".

Returns the same as `lru_cache(maxsize=None)`, creating a thin wrapper around a dictionary lookup for the function arguments. Because it never needs to evict old values, this is smaller and faster than *lru_cache()* with a size limit.

For example:

```
@cache
def factorial(n):
    return n * factorial(n-1) if n else 1
```

(continues on next page)

(continued from previous page)

```
>>> factorial(10)      # no previously cached result, makes 11 recursive calls
3628800
>>> factorial(5)       # just looks up cached value result
120
>>> factorial(12)      # makes two new recursive calls, the other 10 are cached
479001600
```

The cache is threadsafe so that the wrapped function can be used in multiple threads. This means that the underlying data structure will remain coherent during concurrent updates.

It is possible for the wrapped function to be called more than once if another thread makes an additional call before the initial call has been completed and cached.

Added in version 3.9.

`@functools.`**cached_property**(*func*)

Transform a method of a class into a property whose value is computed once and then cached as a normal attribute for the life of the instance. Similar to *property()*, with the addition of caching. Useful for expensive computed properties of instances that are otherwise effectively immutable.

Example:

```
class DataSet:

    def __init__(self, sequence_of_numbers):
        self._data = tuple(sequence_of_numbers)

    @cached_property
    def stdev(self):
        return statistics.stdev(self._data)
```

The mechanics of *cached_property()* are somewhat different from *property()*. A regular property blocks attribute writes unless a setter is defined. In contrast, a *cached_property* allows writes.

The *cached_property* decorator only runs on lookups and only when an attribute of the same name doesn't exist. When it does run, the *cached_property* writes to the attribute with the same name. Subsequent attribute reads and writes take precedence over the *cached_property* method and it works like a normal attribute.

The cached value can be cleared by deleting the attribute. This allows the *cached_property* method to run again.

The *cached_property* does not prevent a possible race condition in multi-threaded usage. The getter function could run more than once on the same instance, with the latest run setting the cached value. If the cached property is idempotent or otherwise not harmful to run more than once on an instance, this is fine. If synchronization is needed, implement the necessary locking inside the decorated getter function or around the cached property access.

Note, this decorator interferes with the operation of **PEP 412** key-sharing dictionaries. This means that instance dictionaries can take more space than usual.

Also, this decorator requires that the `__dict__` attribute on each instance be a mutable mapping. This means it will not work with some types, such as metaclasses (since the `__dict__` attributes on type instances are read-only proxies for the class namespace), and those that specify `__slots__` without including `__dict__` as one of the defined slots (as such classes don't provide a `__dict__` attribute at all).

If a mutable mapping is not available or if space-efficient key sharing is desired, an effect similar to *cached_property()* can also be achieved by stacking *property()* on top of *lru_cache()*. See faq-cache-method-calls for more details on how this differs from *cached_property()*.

Added in version 3.8.

Changed in version 3.12: Prior to Python 3.12, `cached_property` included an undocumented lock to ensure that in multi-threaded usage the getter function was guaranteed to run only once per instance. However, the

lock was per-property, not per-instance, which could result in unacceptably high lock contention. In Python 3.12+ this locking is removed.

`functools.`**`cmp_to_key`**(*func*)

Transform an old-style comparison function to a *key function*. Used with tools that accept key functions (such as *sorted()*, *min()*, *max()*, *heapq.nlargest()*, *heapq.nsmallest()*, *itertools.groupby()*). This function is primarily used as a transition tool for programs being converted from Python 2 which supported the use of comparison functions.

A comparison function is any callable that accepts two arguments, compares them, and returns a negative number for less-than, zero for equality, or a positive number for greater-than. A key function is a callable that accepts one argument and returns another value to be used as the sort key.

Example:

```
sorted(iterable, key=cmp_to_key(locale.strcoll))  # locale-aware sort order
```

For sorting examples and a brief sorting tutorial, see sortinghowto.

Added in version 3.2.

`@functools.`**`lru_cache`**(*user_function*)

`@functools.`**`lru_cache`**(*maxsize=128*, *typed=False*)

Decorator to wrap a function with a memoizing callable that saves up to the *maxsize* most recent calls. It can save time when an expensive or I/O bound function is periodically called with the same arguments.

The cache is threadsafe so that the wrapped function can be used in multiple threads. This means that the underlying data structure will remain coherent during concurrent updates.

It is possible for the wrapped function to be called more than once if another thread makes an additional call before the initial call has been completed and cached.

Since a dictionary is used to cache results, the positional and keyword arguments to the function must be *hashable*.

Distinct argument patterns may be considered to be distinct calls with separate cache entries. For example, `f(a=1, b=2)` and `f(b=2, a=1)` differ in their keyword argument order and may have two separate cache entries.

If *user_function* is specified, it must be a callable. This allows the *lru_cache* decorator to be applied directly to a user function, leaving the *maxsize* at its default value of 128:

```
@lru_cache
def count_vowels(sentence):
    return sum(sentence.count(vowel) for vowel in 'AEIOUaeiou')
```

If *maxsize* is set to `None`, the LRU feature is disabled and the cache can grow without bound.

If *typed* is set to true, function arguments of different types will be cached separately. If *typed* is false, the implementation will usually regard them as equivalent calls and only cache a single result. (Some types such as *str* and *int* may be cached separately even when *typed* is false.)

Note, type specificity applies only to the function's immediate arguments rather than their contents. The scalar arguments, `Decimal(42)` and `Fraction(42)` are be treated as distinct calls with distinct results. In contrast, the tuple arguments `('answer', Decimal(42))` and `('answer', Fraction(42))` are treated as equivalent.

The wrapped function is instrumented with a `cache_parameters()` function that returns a new *dict* showing the values for *maxsize* and *typed*. This is for information purposes only. Mutating the values has no effect.

To help measure the effectiveness of the cache and tune the *maxsize* parameter, the wrapped function is instrumented with a `cache_info()` function that returns a *named tuple* showing *hits*, *misses*, *maxsize* and *currsize*.

The decorator also provides a `cache_clear()` function for clearing or invalidating the cache.

The original underlying function is accessible through the `__wrapped__` attribute. This is useful for introspection, for bypassing the cache, or for rewrapping the function with a different cache.

The cache keeps references to the arguments and return values until they age out of the cache or until the cache is cleared.

If a method is cached, the `self` instance argument is included in the cache. See faq-cache-method-calls

An LRU (least recently used) cache works best when the most recent calls are the best predictors of upcoming calls (for example, the most popular articles on a news server tend to change each day). The cache's size limit assures that the cache does not grow without bound on long-running processes such as web servers.

In general, the LRU cache should only be used when you want to reuse previously computed values. Accordingly, it doesn't make sense to cache functions with side-effects, functions that need to create distinct mutable objects on each call (such as generators and async functions), or impure functions such as time() or random().

Example of an LRU cache for static web content:

```
@lru_cache(maxsize=32)
def get_pep(num):
    'Retrieve text of a Python Enhancement Proposal'
    resource = f'https://peps.python.org/pep-{num:04d}'
    try:
        with urllib.request.urlopen(resource) as s:
            return s.read()
    except urllib.error.HTTPError:
        return 'Not Found'

>>> for n in 8, 290, 308, 320, 8, 218, 320, 279, 289, 320, 9991:
...     pep = get_pep(n)
...     print(n, len(pep))

>>> get_pep.cache_info()
CacheInfo(hits=3, misses=8, maxsize=32, currsize=8)
```

Example of efficiently computing Fibonacci numbers using a cache to implement a dynamic programming technique:

```
@lru_cache(maxsize=None)
def fib(n):
    if n < 2:
        return n
    return fib(n-1) + fib(n-2)

>>> [fib(n) for n in range(16)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610]

>>> fib.cache_info()
CacheInfo(hits=28, misses=16, maxsize=None, currsize=16)
```

Added in version 3.2.

Changed in version 3.3: Added the *typed* option.

Changed in version 3.8: Added the *user_function* option.

Changed in version 3.9: Added the function `cache_parameters()`

`@functools.total_ordering`

Given a class defining one or more rich comparison ordering methods, this class decorator supplies the rest. This simplifies the effort involved in specifying all of the possible rich comparison operations:

The class must define one of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`. In addition, the class should supply an `__eq__()` method.

For example:

```
@total_ordering
class Student:
    def _is_valid_operand(self, other):
        return (hasattr(other, "lastname") and
                hasattr(other, "firstname"))
    def __eq__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

Note

While this decorator makes it easy to create well behaved totally ordered types, it *does* come at the cost of slower execution and more complex stack traces for the derived comparison methods. If performance benchmarking indicates this is a bottleneck for a given application, implementing all six rich comparison methods instead is likely to provide an easy speed boost.

Note

This decorator makes no attempt to override methods that have been declared in the class *or its superclasses*. Meaning that if a superclass defines a comparison operator, *total_ordering* will not implement it again, even if the original method is abstract.

Added in version 3.2.

Changed in version 3.4: Returning `NotImplemented` from the underlying comparison function for unrecognised types is now supported.

`functools.`**`partial`**(*func*, */*, **args*, ***keywords*)

Return a new *partial object* which when called will behave like *func* called with the positional arguments *args* and keyword arguments *keywords*. If more arguments are supplied to the call, they are appended to *args*. If additional keyword arguments are supplied, they extend and override *keywords*. Roughly equivalent to:

```
def partial(func, /, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = {**keywords, **fkeywords}
        return func(*args, *fargs, **newkeywords)
    newfunc.func = func
    newfunc.args = args
    newfunc.keywords = keywords
    return newfunc
```

The *partial()* is used for partial function application which "freezes" some portion of a function's arguments and/or keywords resulting in a new object with a simplified signature. For example, *partial()* can be used to create a callable that behaves like the *int()* function where the *base* argument defaults to two:

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18
```

class functools.**partialmethod**(*func*, /, **args*, ***keywords*)

Return a new *partialmethod* descriptor which behaves like *partial* except that it is designed to be used as a method definition rather than being directly callable.

func must be a *descriptor* or a callable (objects which are both, like normal functions, are handled as descriptors).

When *func* is a descriptor (such as a normal Python function, *classmethod()*, *staticmethod()*, abstractmethod() or another instance of *partialmethod*), calls to __get__ are delegated to the underlying descriptor, and an appropriate *partial object* returned as the result.

When *func* is a non-descriptor callable, an appropriate bound method is created dynamically. This behaves like a normal Python function when used as a method: the *self* argument will be inserted as the first positional argument, even before the *args* and *keywords* supplied to the *partialmethod* constructor.

Example:

```
>>> class Cell:
...     def __init__(self):
...         self._alive = False
...     @property
...     def alive(self):
...         return self._alive
...     def set_state(self, state):
...         self._alive = bool(state)
...     set_alive = partialmethod(set_state, True)
...     set_dead = partialmethod(set_state, False)
...
>>> c = Cell()
>>> c.alive
False
>>> c.set_alive()
>>> c.alive
True
```

Added in version 3.4.

functools.**reduce**(*function*, *iterable*, [*initial*,]/)

Apply *function* of two arguments cumulatively to the items of *iterable*, from left to right, so as to reduce the iterable to a single value. For example, reduce(lambda x, y: x+y, [1, 2, 3, 4, 5]) calculates ((((1+2)+3)+4)+5). The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *iterable*. If the optional *initial* is present, it is placed before the items of the iterable in the calculation, and serves as a default when the iterable is empty. If *initial* is not given and *iterable* contains only one item, the first item is returned.

Roughly equivalent to:

```
initial_missing = object()

def reduce(function, iterable, initial=initial_missing, /):
    it = iter(iterable)
    if initial is initial_missing:
        value = next(it)
    else:
```

(continues on next page)

(continued from previous page)

```
        value = initial
    for element in it:
        value = function(value, element)
    return value
```

See *itertools.accumulate()* for an iterator that yields all intermediate values.

`@functools.`**`singledispatch`**

Transform a function into a *single-dispatch generic function*.

To define a generic function, decorate it with the `@singledispatch` decorator. When defining a function using `@singledispatch`, note that the dispatch happens on the type of the first argument:

```
>>> from functools import singledispatch
>>> @singledispatch
... def fun(arg, verbose=False):
...     if verbose:
...         print("Let me just say,", end=" ")
...     print(arg)
```

To add overloaded implementations to the function, use the `register()` attribute of the generic function, which can be used as a decorator. For functions annotated with types, the decorator will infer the type of the first argument automatically:

```
>>> @fun.register
... def _(arg: int, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> @fun.register
... def _(arg: list, verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
```

types.UnionType and *typing.Union* can also be used:

```
>>> @fun.register
... def _(arg: int | float, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> from typing import Union
>>> @fun.register
... def _(arg: Union[list, set], verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
...
```

For code which doesn't use type annotations, the appropriate type argument can be passed explicitly to the decorator itself:

```
>>> @fun.register(complex)
... def _(arg, verbose=False):
...     if verbose:
...         print("Better than complicated.", end=" ")
...     print(arg.real, arg.imag)
...
```

For code that dispatches on a collections type (e.g., `list`), but wants to typehint the items of the collection (e.g., `list[int]`), the dispatch type should be passed explicitly to the decorator itself with the typehint going into the function definition:

```
>>> @fun.register(list)
... def _(arg: list[int], verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
```

Note

At runtime the function will dispatch on an instance of a list regardless of the type contained within the list i.e. `[1,2,3]` will be dispatched the same as `["foo", "bar", "baz"]`. The annotation provided in this example is for static type checkers only and has no runtime impact.

To enable registering *lambdas* and pre-existing functions, the `register()` attribute can also be used in a functional form:

```
>>> def nothing(arg, verbose=False):
...     print("Nothing.")
...
>>> fun.register(type(None), nothing)
```

The `register()` attribute returns the undecorated function. This enables decorator stacking, *pickling*, and the creation of unit tests for each variant independently:

```
>>> @fun.register(float)
... @fun.register(Decimal)
... def fun_num(arg, verbose=False):
...     if verbose:
...         print("Half of your number:", end=" ")
...     print(arg / 2)
...
>>> fun_num is fun
False
```

When called, the generic function dispatches on the type of the first argument:

```
>>> fun("Hello, world.")
Hello, world.
>>> fun("test.", verbose=True)
Let me just say, test.
>>> fun(42, verbose=True)
Strength in numbers, eh? 42
>>> fun(['spam', 'spam', 'eggs', 'spam'], verbose=True)
Enumerate this:
0 spam
```

(continues on next page)

(continued from previous page)

```
1 spam
2 eggs
3 spam
>>> fun(None)
Nothing.
>>> fun(1.23)
0.615
```

Where there is no registered implementation for a specific type, its method resolution order is used to find a more generic implementation. The original function decorated with `@singledispatch` is registered for the base *object* type, which means it is used if no better implementation is found.

If an implementation is registered to an *abstract base class*, virtual subclasses of the base class will be dispatched to that implementation:

```
>>> from collections.abc import Mapping
>>> @fun.register
... def _(arg: Mapping, verbose=False):
...     if verbose:
...         print("Keys & Values")
...     for key, value in arg.items():
...         print(key, "=>", value)
...
>>> fun({"a": "b"})
a => b
```

To check which implementation the generic function will choose for a given type, use the `dispatch()` attribute:

```
>>> fun.dispatch(float)
<function fun_num at 0x1035a2840>
>>> fun.dispatch(dict)    # note: default implementation
<function fun at 0x103fe0000>
```

To access all registered implementations, use the read-only `registry` attribute:

```
>>> fun.registry.keys()
dict_keys([<class 'NoneType'>, <class 'int'>, <class 'object'>,
           <class 'decimal.Decimal'>, <class 'list'>,
           <class 'float'>])
>>> fun.registry[float]
<function fun_num at 0x1035a2840>
>>> fun.registry[object]
<function fun at 0x103fe0000>
```

Added in version 3.4.

Changed in version 3.7: The `register()` attribute now supports using type annotations.

Changed in version 3.11: The `register()` attribute now supports *types.UnionType* and *typing.Union* as type annotations.

class functools.**singledispatchmethod**(*func*)

Transform a method into a *single-dispatch generic function*.

To define a generic method, decorate it with the `@singledispatchmethod` decorator. When defining a function using `@singledispatchmethod`, note that the dispatch happens on the type of the first non-*self* or non-*cls* argument:

```
class Negator:
    @singledispatchmethod
    def neg(self, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    def _(self, arg: int):
        return -arg

    @neg.register
    def _(self, arg: bool):
        return not arg
```

`@singledispatchmethod` supports nesting with other decorators such as *`@classmethod`*. Note that to allow for `dispatcher.register`, `singledispatchmethod` must be the *outer most* decorator. Here is the `Negator` class with the `neg` methods bound to the class, rather than an instance of the class:

```
class Negator:
    @singledispatchmethod
    @classmethod
    def neg(cls, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    @classmethod
    def _(cls, arg: int):
        return -arg

    @neg.register
    @classmethod
    def _(cls, arg: bool):
        return not arg
```

The same pattern can be used for other similar decorators: *`@staticmethod`*, *`@abstractmethod`*, and others.

Added in version 3.8.

`functools.`**`update_wrapper`**(*wrapper*, *wrapped*, *assigned=WRAPPER_ASSIGNMENTS*, *updated=WRAPPER_UPDATES*)

Update a *wrapper* function to look like the *wrapped* function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function's `__module__`, `__name__`, `__qualname__`, `__annotations__`, `__type_params__`, and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function's `__dict__`, i.e. the instance dictionary).

To allow access to the original function for introspection and other purposes (e.g. bypassing a caching decorator such as *`lru_cache()`*), this function automatically adds a `__wrapped__` attribute to the wrapper that refers to the function being wrapped.

The main intended use for this function is in *decorator* functions which wrap the decorated function and return the wrapper. If the wrapper function is not updated, the metadata of the returned function will reflect the wrapper definition rather than the original function definition, which is typically less than helpful.

`update_wrapper()` may be used with callables other than functions. Any attributes named in *assigned* or *updated* that are missing from the object being wrapped are ignored (i.e. this function will not attempt to set them on the wrapper function). *`AttributeError`* is still raised if the wrapper function itself is missing any attributes named in *updated*.

Changed in version 3.2: The `__wrapped__` attribute is now automatically added. The `__annotations__` attribute is now copied by default. Missing attributes no longer trigger an *`AttributeError`*.

Changed in version 3.4: The `__wrapped__` attribute now always refers to the wrapped function, even if that function defined a `__wrapped__` attribute. (see bpo-17482)

Changed in version 3.12: The `__type_params__` attribute is now copied by default.

`@functools.`**`wraps`**(*wrapped*, *assigned=WRAPPER_ASSIGNMENTS*, *updated=WRAPPER_UPDATES*)

This is a convenience function for invoking *`update_wrapper()`* as a function decorator when defining a wrapper function. It is equivalent to `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. For example:

```
>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kwds):
...         print('Calling decorated function')
...         return f(*args, **kwds)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print('Called example function')
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'
```

Without the use of this decorator factory, the name of the example function would have been `'wrapper'`, and the docstring of the original `example()` would have been lost.

10.2.1 `partial` Objects

`partial` objects are callable objects created by *`partial()`*. They have three read-only attributes:

`partial.`**`func`**

A callable object or function. Calls to the *`partial`* object will be forwarded to *`func`* with new arguments and keywords.

`partial.`**`args`**

The leftmost positional arguments that will be prepended to the positional arguments provided to a *`partial`* object call.

`partial.`**`keywords`**

The keyword arguments that will be supplied when the *`partial`* object is called.

`partial` objects are like function objects in that they are callable, weak referenceable, and can have attributes. There are some important differences. For instance, the `__name__` and `function.__doc__` attributes are not created automatically. Also, *`partial`* objects defined in classes behave like static methods and do not transform into bound methods during instance attribute look-up.

10.3 operator — Standard operators as functions

Source code: Lib/operator.py

The *operator* module exports a set of efficient functions corresponding to the intrinsic operators of Python. For example, `operator.add(x, y)` is equivalent to the expression `x+y`. Many function names are those used for special methods, without the double underscores. For backward compatibility, many of these have a variant with the double underscores kept. The variants without the double underscores are preferred for clarity.

The functions fall into categories that perform object comparisons, logical operations, mathematical operations and sequence operations.

The object comparison functions are useful for all objects, and are named after the rich comparison operators they support:

operator.**lt**(*a*, *b*)

operator.**le**(*a*, *b*)

operator.**eq**(*a*, *b*)

operator.**ne**(*a*, *b*)

operator.**ge**(*a*, *b*)

operator.**gt**(*a*, *b*)

operator.**__lt__**(*a*, *b*)

operator.**__le__**(*a*, *b*)

operator.**__eq__**(*a*, *b*)

operator.**__ne__**(*a*, *b*)

operator.**__ge__**(*a*, *b*)

operator.**__gt__**(*a*, *b*)

> Perform "rich comparisons" between *a* and *b*. Specifically, `lt(a, b)` is equivalent to `a < b`, `le(a, b)` is equivalent to `a <= b`, `eq(a, b)` is equivalent to `a == b`, `ne(a, b)` is equivalent to `a != b`, `gt(a, b)` is equivalent to `a > b` and `ge(a, b)` is equivalent to `a >= b`. Note that these functions can return any value, which may or may not be interpretable as a Boolean value. See comparisons for more information about rich comparisons.

The logical operations are also generally applicable to all objects, and support truth tests, identity tests, and boolean operations:

operator.**not_**(*obj*)

operator.**__not__**(*obj*)

> Return the outcome of `not` *obj*. (Note that there is no `__not__()` method for object instances; only the interpreter core defines this operation. The result is affected by the `__bool__()` and `__len__()` methods.)

operator.**truth**(*obj*)

> Return *True* if *obj* is true, and *False* otherwise. This is equivalent to using the *bool* constructor.

operator.**is_**(*a*, *b*)

> Return `a is b`. Tests object identity.

operator.**is_not**(*a*, *b*)

> Return `a is not b`. Tests object identity.

The mathematical and bitwise operations are the most numerous:

operator.**abs**(*obj*)

operator.**__abs__**(*obj*)

> Return the absolute value of *obj*.

operator.**add**(*a*, *b*)

operator.**__add__**(*a*, *b*)

Return `a + b`, for *a* and *b* numbers.

operator.**and_**(*a*, *b*)

operator.**__and__**(*a*, *b*)

Return the bitwise and of *a* and *b*.

operator.**floordiv**(*a*, *b*)

operator.**__floordiv__**(*a*, *b*)

Return `a // b`.

operator.**index**(*a*)

operator.**__index__**(*a*)

Return *a* converted to an integer. Equivalent to `a.__index__()`.

Changed in version 3.10: The result always has exact type *int*. Previously, the result could have been an instance of a subclass of `int`.

operator.**inv**(*obj*)

operator.**invert**(*obj*)

operator.**__inv__**(*obj*)

operator.**__invert__**(*obj*)

Return the bitwise inverse of the number *obj*. This is equivalent to `~obj`.

operator.**lshift**(*a*, *b*)

operator.**__lshift__**(*a*, *b*)

Return *a* shifted left by *b*.

operator.**mod**(*a*, *b*)

operator.**__mod__**(*a*, *b*)

Return `a % b`.

operator.**mul**(*a*, *b*)

operator.**__mul__**(*a*, *b*)

Return `a * b`, for *a* and *b* numbers.

operator.**matmul**(*a*, *b*)

operator.**__matmul__**(*a*, *b*)

Return `a @ b`.

Added in version 3.5.

operator.**neg**(*obj*)

operator.**__neg__**(*obj*)

Return *obj* negated (`-obj`).

operator.**or_**(*a*, *b*)

operator.**__or__**(*a*, *b*)

Return the bitwise or of *a* and *b*.

operator.**pos**(*obj*)

operator.**__pos__**(*obj*)

Return *obj* positive (`+obj`).

operator.**pow**(*a*, *b*)

operator.**__pow__**(*a*, *b*)

Return `a ** b`, for *a* and *b* numbers.

operator.**rshift**(*a*, *b*)

operator.**__rshift__**(*a*, *b*)

Return *a* shifted right by *b*.

operator.**sub**(*a*, *b*)

operator.**__sub__**(*a*, *b*)

Return `a - b`.

operator.**truediv**(*a*, *b*)

operator.**__truediv__**(*a*, *b*)

Return `a / b` where 2/3 is .66 rather than 0. This is also known as "true" division.

operator.**xor**(*a*, *b*)

operator.**__xor__**(*a*, *b*)

Return the bitwise exclusive or of *a* and *b*.

Operations which work with sequences (some of them with mappings too) include:

operator.**concat**(*a*, *b*)

operator.**__concat__**(*a*, *b*)

Return `a + b` for *a* and *b* sequences.

operator.**contains**(*a*, *b*)

operator.**__contains__**(*a*, *b*)

Return the outcome of the test `b in a`. Note the reversed operands.

operator.**countOf**(*a*, *b*)

Return the number of occurrences of *b* in *a*.

operator.**delitem**(*a*, *b*)

operator.**__delitem__**(*a*, *b*)

Remove the value of *a* at index *b*.

operator.**getitem**(*a*, *b*)

operator.**__getitem__**(*a*, *b*)

Return the value of *a* at index *b*.

operator.**indexOf**(*a*, *b*)

Return the index of the first of occurrence of *b* in *a*.

operator.**setitem**(*a*, *b*, *c*)

operator.**__setitem__**(*a*, *b*, *c*)

Set the value of *a* at index *b* to *c*.

operator.**length_hint**(*obj*, *default=0*)

Return an estimated length for the object *obj*. First try to return its actual length, then an estimate using `object.__length_hint__()`, and finally return the default value.

Added in version 3.4.

The following operation works with callables:

operator.**call**(*obj*, */*, **args*, ***kwargs*)

operator.**__call__**(*obj*, */*, **args*, ***kwargs*)

Return `obj(*args, **kwargs)`.

Added in version 3.11.

The *operator* module also defines tools for generalized attribute and item lookups. These are useful for making fast field extractors as arguments for *map()*, *sorted()*, *itertools.groupby()*, or other functions that expect a function argument.

operator.**attrgetter**(*attr*)

operator.**attrgetter**(**attrs*)

Return a callable object that fetches *attr* from its operand. If more than one attribute is requested, returns a tuple of attributes. The attribute names can also contain dots. For example:

- After `f = attrgetter('name')`, the call `f(b)` returns `b.name`.
- After `f = attrgetter('name', 'date')`, the call `f(b)` returns `(b.name, b.date)`.
- After `f = attrgetter('name.first', 'name.last')`, the call `f(b)` returns `(b.name.first, b.name.last)`.

Equivalent to:

```
def attrgetter(*items):
    if any(not isinstance(item, str) for item in items):
        raise TypeError('attribute name must be a string')
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj
```

operator.**itemgetter**(*item*)

operator.**itemgetter**(**items*)

Return a callable object that fetches *item* from its operand using the operand's `__getitem__()` method. If multiple items are specified, returns a tuple of lookup values. For example:

- After `f = itemgetter(2)`, the call `f(r)` returns `r[2]`.
- After `g = itemgetter(2, 5, 3)`, the call `g(r)` returns `(r[2], r[5], r[3])`.

Equivalent to:

```
def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g
```

The items can be any type accepted by the operand's `__getitem__()` method. Dictionaries accept any *hashable* value. Lists, tuples, and strings accept an index or a slice:

```
>>> itemgetter(1)('ABCDEFG')
'B'
>>> itemgetter(1, 3, 5)('ABCDEFG')
('B', 'D', 'F')
>>> itemgetter(slice(2, None))('ABCDEFG')
'CDEFG'
>>> soldier = dict(rank='captain', name='dotterbart')
```

(continues on next page)

(continued from previous page)

```
>>> itemgetter('rank')(soldier)
'captain'
```

Example of using *itemgetter()* to retrieve specific fields from a tuple record:

```
>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> list(map(getcount, inventory))
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]
```

operator.**methodcaller**(*name*, */*, **args*, ***kwargs*)

Return a callable object that calls the method *name* on its operand. If additional arguments and/or keyword arguments are given, they will be given to the method as well. For example:

- After `f = methodcaller('name')`, the call `f(b)` returns `b.name()`.
- After `f = methodcaller('name', 'foo', bar=1)`, the call `f(b)` returns `b.name('foo', bar=1)`.

Equivalent to:

```
def methodcaller(name, /, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

10.3.1 Mapping Operators to Functions

This table shows how abstract operations correspond to operator symbols in the Python syntax and the functions in the *operator* module.

Operation	Syntax	Function
Addition	`a + b`	`add(a, b)`
Concatenation	`seq1 + seq2`	`concat(seq1, seq2)`
Containment Test	`obj in seq`	`contains(seq, obj)`
Division	`a / b`	`truediv(a, b)`
Division	`a // b`	`floordiv(a, b)`
Bitwise And	`a & b`	`and_(a, b)`
Bitwise Exclusive Or	`a ^ b`	`xor(a, b)`
Bitwise Inversion	`~ a`	`invert(a)`
Bitwise Or	`a | b`	`or_(a, b)`
Exponentiation	`a ** b`	`pow(a, b)`
Identity	`a is b`	`is_(a, b)`
Identity	`a is not b`	`is_not(a, b)`
Indexed Assignment	`obj[k] = v`	`setitem(obj, k, v)`
Indexed Deletion	`del obj[k]`	`delitem(obj, k)`
Indexing	`obj[k]`	`getitem(obj, k)`
Left Shift	`a << b`	`lshift(a, b)`
Modulo	`a % b`	`mod(a, b)`
Multiplication	`a * b`	`mul(a, b)`
Matrix Multiplication	`a @ b`	`matmul(a, b)`
Negation (Arithmetic)	`- a`	`neg(a)`
Negation (Logical)	`not a`	`not_(a)`
Positive	`+ a`	`pos(a)`

continues on next page

Table 1 – continued from previous page

Operation	Syntax	Function
Right Shift	`a >> b`	`rshift(a, b)`
Slice Assignment	`seq[i:j] = values`	`setitem(seq, slice(i, j), values)`
Slice Deletion	`del seq[i:j]`	`delitem(seq, slice(i, j))`
Slicing	`seq[i:j]`	`getitem(seq, slice(i, j))`
String Formatting	`s % obj`	`mod(s, obj)`
Subtraction	`a - b`	`sub(a, b)`
Truth Test	`obj`	`truth(obj)`
Ordering	`a < b`	`lt(a, b)`
Ordering	`a <= b`	`le(a, b)`
Equality	`a == b`	`eq(a, b)`
Difference	`a != b`	`ne(a, b)`
Ordering	`a >= b`	`ge(a, b)`
Ordering	`a > b`	`gt(a, b)`

10.3.2 In-place Operators

Many operations have an "in-place" version. Listed below are functions providing a more primitive access to in-place operators than the usual syntax does; for example, the *statement* `x += y` is equivalent to `x = operator.iadd(x, y)`. Another way to put it is to say that `z = operator.iadd(x, y)` is equivalent to the compound statement `z = x; z += y`.

In those examples, note that when an in-place method is called, the computation and assignment are performed in two separate steps. The in-place functions listed below only do the first step, calling the in-place method. The second step, assignment, is not handled.

For immutable targets such as strings, numbers, and tuples, the updated value is computed, but not assigned back to the input variable:

```
>>> a = 'hello'
>>> iadd(a, ' world')
'hello world'
>>> a
'hello'
```

For mutable targets such as lists and dictionaries, the in-place method will perform the update, so no subsequent assignment is necessary:

```
>>> s = ['h', 'e', 'l', 'l', 'o']
>>> iadd(s, [' ', 'w', 'o', 'r', 'l', 'd'])
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
>>> s
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
```

operator.**iadd**(*a*, *b*)

operator.**__iadd__**(*a*, *b*)

`a = iadd(a, b)` is equivalent to `a += b`.

operator.**iand**(*a*, *b*)

operator.**__iand__**(*a*, *b*)

`a = iand(a, b)` is equivalent to `a &= b`.

operator.**iconcat**(*a*, *b*)

operator.**__iconcat__**(*a*, *b*)

`a = iconcat(a, b)` is equivalent to `a += b` for *a* and *b* sequences.

operator.**ifloordiv**(*a*, *b*)

operator.**__ifloordiv__**(*a*, *b*)

`a = ifloordiv(a, b)` is equivalent to `a //= b`.

operator.**ilshift**(*a*, *b*)

operator.**__ilshift__**(*a*, *b*)

`a = ilshift(a, b)` is equivalent to `a <<= b`.

operator.**imod**(*a*, *b*)

operator.**__imod__**(*a*, *b*)

`a = imod(a, b)` is equivalent to `a %= b`.

operator.**imul**(*a*, *b*)

operator.**__imul__**(*a*, *b*)

`a = imul(a, b)` is equivalent to `a *= b`.

operator.**imatmul**(*a*, *b*)

operator.**__imatmul__**(*a*, *b*)

`a = imatmul(a, b)` is equivalent to `a @= b`.

Added in version 3.5.

operator.**ior**(*a*, *b*)

operator.**__ior__**(*a*, *b*)

`a = ior(a, b)` is equivalent to `a |= b`.

operator.**ipow**(*a*, *b*)

operator.**__ipow__**(*a*, *b*)

`a = ipow(a, b)` is equivalent to `a **= b`.

operator.**irshift**(*a*, *b*)

operator.**__irshift__**(*a*, *b*)

`a = irshift(a, b)` is equivalent to `a >>= b`.

operator.**isub**(*a*, *b*)

operator.**__isub__**(*a*, *b*)

`a = isub(a, b)` is equivalent to `a -= b`.

operator.**itruediv**(*a*, *b*)

operator.**__itruediv__**(*a*, *b*)

`a = itruediv(a, b)` is equivalent to `a /= b`.

operator.**ixor**(*a*, *b*)

operator.**__ixor__**(*a*, *b*)

`a = ixor(a, b)` is equivalent to `a ^= b`.

CHAPTER

ELEVEN

FILE AND DIRECTORY ACCESS

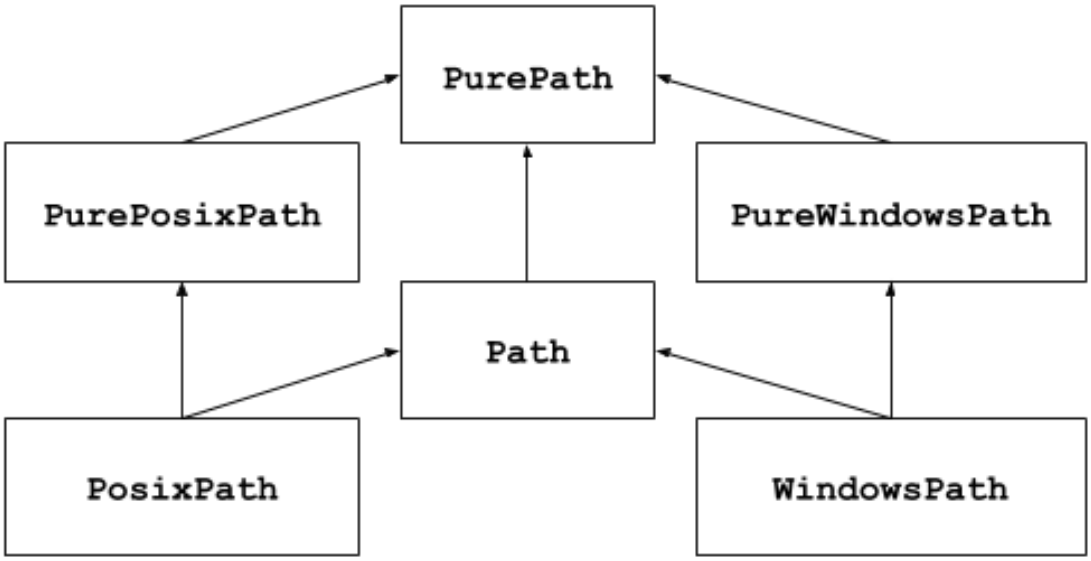
The modules described in this chapter deal with disk files and directories. For example, there are modules for reading the properties of files, manipulating paths in a portable way, and creating temporary files. The full list of modules in this chapter is:

11.1 `pathlib` — Object-oriented filesystem paths

Added in version 3.4.

Source code: Lib/pathlib/

This module offers classes representing filesystem paths with semantics appropriate for different operating systems. Path classes are divided between *pure paths*, which provide purely computational operations without I/O, and *concrete paths*, which inherit from pure paths but also provide I/O operations.



If you've never used this module before or just aren't sure which class is right for your task, `Path` is most likely what you need. It instantiates a *concrete path* for the platform the code is running on.

Pure paths are useful in some special cases; for example:

1. If you want to manipulate Windows paths on a Unix machine (or vice versa). You cannot instantiate a `WindowsPath` when running on Unix, but you can instantiate `PureWindowsPath`.

2. You want to make sure that your code only manipulates paths without actually accessing the OS. In this case, instantiating one of the pure classes may be useful since those simply don't have any OS-accessing operations.

See also

PEP 428: The pathlib module – object-oriented filesystem paths.

See also

For low-level path manipulation on strings, you can also use the *os.path* module.

11.1.1 Basic use

Importing the main class:

```
>>> from pathlib import Path
```

Listing subdirectories:

```
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
 PosixPath('__pycache__'), PosixPath('build')]
```

Listing Python source files in this directory tree:

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
 PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
 PosixPath('build/lib/pathlib.py')]
```

Navigating inside a directory tree:

```
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

Querying path properties:

```
>>> q.exists()
True
>>> q.is_dir()
False
```

Opening a file:

```
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

11.1.2 Exceptions

exception pathlib.**UnsupportedOperation**

An exception inheriting *NotImplementedError* that is raised when an unsupported operation is called on a path object.

Added in version 3.13.

11.1.3 Pure paths

Pure path objects provide path-handling operations which don't actually access a filesystem. There are three ways to access these classes, which we also call *flavours*:

class pathlib.**PurePath**(**pathsegments*)

A generic class that represents the system's path flavour (instantiating it creates either a *PurePosixPath* or a *PureWindowsPath*):

```
>>> PurePath('setup.py')      # Running on a Unix machine
PurePosixPath('setup.py')
```

Each element of *pathsegments* can be either a string representing a path segment, or an object implementing the *os.PathLike* interface where the *__fspath__()* method returns a string, such as another path object:

```
>>> PurePath('foo', 'some/path', 'bar')
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

When *pathsegments* is empty, the current directory is assumed:

```
>>> PurePath()
PurePosixPath('.')
```

If a segment is an absolute path, all previous segments are ignored (like *os.path.join()*):

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

On Windows, the drive is not reset when a rooted relative path segment (e.g., `r'\foo'`) is encountered:

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

Spurious slashes and single dots are collapsed, but double dots (`'..'`) and leading double slashes (`'//'`) are not, since this would change the meaning of a path for various reasons (e.g. symbolic links, UNC paths):

```
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('//foo/bar')
PurePosixPath('//foo/bar')
>>> PurePath('foo/./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/../bar')
PurePosixPath('foo/../bar')
```

(a naïve approach would make `PurePosixPath('foo/../bar')` equivalent to `PurePosixPath('bar')`, which is wrong if `foo` is a symbolic link to another directory)

Pure path objects implement the *os.PathLike* interface, allowing them to be used anywhere the interface is accepted.

Changed in version 3.6: Added support for the *os.PathLike* interface.

class pathlib.**PurePosixPath**(**pathsegments*)

A subclass of *PurePath*, this path flavour represents non-Windows filesystem paths:

```
>>> PurePosixPath('/etc/hosts')
PurePosixPath('/etc/hosts')
```

pathsegments is specified similarly to *PurePath*.

class pathlib.**PureWindowsPath**(**pathsegments*)

A subclass of *PurePath*, this path flavour represents Windows filesystem paths, including UNC paths:

```
>>> PureWindowsPath('c:/', 'Users', 'Ximénez')
PureWindowsPath('c:/Users/Ximénez')
>>> PureWindowsPath('//server/share/file')
PureWindowsPath('//server/share/file')
```

pathsegments is specified similarly to *PurePath*.

Regardless of the system you're running on, you can instantiate all of these classes, since they don't provide any operation that does system calls.

General properties

Paths are immutable and *hashable*. Paths of a same flavour are comparable and orderable. These properties respect the flavour's case-folding semantics:

```
>>> PurePosixPath('foo') == PurePosixPath('FOO')
False
>>> PureWindowsPath('foo') == PureWindowsPath('FOO')
True
>>> PureWindowsPath('FOO') in { PureWindowsPath('foo') }
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True
```

Paths of a different flavour compare unequal and cannot be ordered:

```
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureWindowsPath' and
↪'PurePosixPath'
```

Operators

The slash operator helps create child paths, like *os.path.join()*. If the argument is an absolute path, the previous path is ignored. On Windows, the drive is not reset when the argument is a rooted relative path (e.g., `r'\foo'`):

```
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
```

(continues on next page)

(continued from previous page)

```
>>> q = PurePath('bin')
>>> '/usr' / q
PurePosixPath('/usr/bin')
>>> p / '/an_absolute_path'
PurePosixPath('/an_absolute_path')
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

A path object can be used anywhere an object implementing *os.PathLike* is accepted:

```
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

The string representation of a path is the raw filesystem path itself (in native form, e.g. with backslashes under Windows), which you can pass to any function taking a file path as a string:

```
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

Similarly, calling *bytes* on a path gives the raw filesystem path as a bytes object, as encoded by *os.fsencode()*:

```
>>> bytes(p)
b'/etc'
```

Note

Calling *bytes* is only recommended under Unix. Under Windows, the unicode form is the canonical representation of filesystem paths.

Accessing individual parts

To access the individual "parts" (components) of a path, use the following property:

`PurePath.`**`parts`**

A tuple giving access to the path's various components:

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')

>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

(note how the drive and local root are regrouped in a single part)

Methods and properties

Pure paths provide the following methods and properties:

`PurePath.`**`parser`**

The implementation of the *os.path* module used for low-level path parsing and joining: either `posixpath` or `ntpath`.

Added in version 3.13.

`PurePath.`**`drive`**

A string representing the drive letter or name, if any:

```
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
>>> PurePosixPath('/etc').drive
''
```

UNC shares are also considered drives:

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\\host\\share'
```

`PurePath.`**`root`**

A string representing the (local or global) root, if any:

```
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
'/'
```

UNC shares always have a root:

```
>>> PureWindowsPath('//host/share').root
'\\'
```

If the path starts with more than two successive slashes, *PurePosixPath* collapses them:

```
>>> PurePosixPath('//etc').root
'//'
>>> PurePosixPath('///etc').root
'/'
>>> PurePosixPath('////etc').root
'/'
```

Note

This behavior conforms to *The Open Group Base Specifications Issue 6*, paragraph 4.11 Pathname Resolution:

"A pathname that begins with two successive slashes may be interpreted in an implementation-defined manner, although more than two leading slashes shall be treated as a single slash."

`PurePath.`**`anchor`**

The concatenation of the drive and root:

```
>>> PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
'c:'
>>> PurePosixPath('/etc').anchor
'/'
>>> PureWindowsPath('//host/share').anchor
'\\\\host\\share\\'
```

PurePath.**parents**

An immutable sequence providing access to the logical ancestors of the path:

```
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

Changed in version 3.10: The parents sequence now supports *slices* and negative index values.

PurePath.**parent**

The logical parent of the path:

```
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

You cannot go past an anchor, or empty path:

```
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

Note

This is a purely lexical operation, hence the following behaviour:

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

If you want to walk an arbitrary filesystem path upwards, it is recommended to first call *Path.resolve()* so as to resolve symlinks and eliminate `".."` components.

PurePath.**name**

A string representing the final path component, excluding the drive and root, if any:

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC drive names are not considered:

```
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
>>> PureWindowsPath('//some/share').name
''
```

PurePath.**suffix**

The last dot-separated portion of the final component, if any:

```
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

This is commonly called the file extension.

PurePath.**suffixes**

A list of the path's suffixes, often called file extensions:

```
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

PurePath.**stem**

The final path component, without its suffix:

```
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

PurePath.**as_posix**()

Return a string representation of the path with forward slashes (/):

```
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

PurePath.**is_absolute**()

Return whether the path is absolute or not. A path is considered absolute if it has both a root and (if the flavour allows) a drive:

```
>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
False

>>> PureWindowsPath('c:/a/b').is_absolute()
True
```

(continues on next page)

(continued from previous page)

```
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('//some/share').is_absolute()
True
```

PurePath.**is_relative_to**(*other*)

Return whether or not this path is relative to the *other* path.

```
>>> p = PurePath('/etc/passwd')
>>> p.is_relative_to('/etc')
True
>>> p.is_relative_to('/usr')
False
```

This method is string-based; it neither accesses the filesystem nor treats "." segments specially. The following code is equivalent:

```
>>> u = PurePath('/usr')
>>> u == p or u in p.parents
False
```

Added in version 3.9.

Deprecated since version 3.12, will be removed in version 3.14: Passing additional arguments is deprecated; if supplied, they are joined with *other*.

PurePath.**is_reserved**()

With *PureWindowsPath*, return `True` if the path is considered reserved under Windows, `False` otherwise. With *PurePosixPath*, `False` is always returned.

Changed in version 3.13: Windows path names that contain a colon, or end with a dot or a space, are considered reserved. UNC paths may be reserved.

Deprecated since version 3.13, will be removed in version 3.15: This method is deprecated; use *os.path.isreserved()* to detect reserved paths on Windows.

PurePath.**joinpath**(**pathsegments*)

Calling this method is equivalent to combining the path with each of the given *pathsegments* in turn:

```
>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('passwd'))
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apache2')
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files')
PureWindowsPath('c:/Program Files')
```

PurePath.**full_match**(*pattern*, ***, *case_sensitive=None*)

Match this path against the provided glob-style pattern. Return `True` if matching is successful, `False` otherwise. For example:

```
>>> PurePath('a/b.py').full_match('a/*.py')
True
>>> PurePath('a/b.py').full_match('*.py')
False
```

(continues on next page)

(continued from previous page)

```
>>> PurePath('/a/b/c.py').full_match('/a/**')
True
>>> PurePath('/a/b/c.py').full_match('**/*.py')
True
```

See also

Pattern language documentation.

As with other methods, case-sensitivity follows platform defaults:

```
>>> PurePosixPath('b.py').full_match('*.PY')
False
>>> PureWindowsPath('b.py').full_match('*.PY')
True
```

Set *case_sensitive* to `True` or `False` to override this behaviour.

Added in version 3.13.

`PurePath.`**`match`**(*pattern*, *, *case_sensitive=None*)

Match this path against the provided non-recursive glob-style pattern. Return `True` if matching is successful, `False` otherwise.

This method is similar to *`full_match()`*, but empty patterns aren't allowed (*`ValueError`* is raised), the recursive wildcard "`**`" isn't supported (it acts like non-recursive "`*`"), and if a relative pattern is provided, then matching is done from the right:

```
>>> PurePath('a/b.py').match('*.py')
True
>>> PurePath('/a/b/c.py').match('b/*.py')
True
>>> PurePath('/a/b/c.py').match('a/*.py')
False
```

Changed in version 3.12: The *pattern* parameter accepts a *path-like object*.

Changed in version 3.12: The *case_sensitive* parameter was added.

`PurePath.`**`relative_to`**(*other*, *walk_up=False*)

Compute a version of this path relative to the path represented by *other*. If it's impossible, *`ValueError`* is raised:

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.relative_to('/')
PurePosixPath('etc/passwd')
>>> p.relative_to('/etc')
PurePosixPath('passwd')
>>> p.relative_to('/usr')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 941, in relative_to
    raise ValueError(error_message.format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not in the subpath of '/usr' OR one path is␣
↪relative and the other is absolute.
```

When *walk_up* is false (the default), the path must start with *other*. When the argument is true, `..` entries may be added to form the relative path. In all other cases, such as the paths referencing different drives,

ValueError is raised.:

```
>>> p.relative_to('/usr', walk_up=True)
PurePosixPath('../etc/passwd')
>>> p.relative_to('foo', walk_up=True)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 941, in relative_to
    raise ValueError(error_message.format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not on the same drive as 'foo' OR one path is␣
↪relative and the other is absolute.
```

Warning

This function is part of *PurePath* and works with strings. It does not check or access the underlying file structure. This can impact the *walk_up* option as it assumes that no symlinks are present in the path; call *resolve()* first if necessary to resolve symlinks.

Changed in version 3.12: The *walk_up* parameter was added (old behavior is the same as `walk_up=False`).

Deprecated since version 3.12, will be removed in version 3.14: Passing additional positional arguments is deprecated; if supplied, they are joined with *other*.

`PurePath.`**`with_name`**`(`*name*`)`

Return a new path with the *name* changed. If the original path doesn't have a name, ValueError is raised:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 751, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

`PurePath.`**`with_stem`**`(`*stem*`)`

Return a new path with the *stem* changed. If the original path doesn't have a name, ValueError is raised:

```
>>> p = PureWindowsPath('c:/Downloads/draft.txt')
>>> p.with_stem('final')
PureWindowsPath('c:/Downloads/final.txt')
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_stem('lib')
PureWindowsPath('c:/Downloads/lib.gz')
>>> p = PureWindowsPath('c:/')
>>> p.with_stem('')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 861, in with_stem
    return self.with_name(stem + self.suffix)
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 851, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

Added in version 3.9.

PurePath.**with_suffix**(*suffix*)

Return a new path with the *suffix* changed. If the original path doesn't have a suffix, the new *suffix* is appended instead. If the *suffix* is an empty string, the original suffix is removed:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README')
```

PurePath.**with_segments**(**pathsegments*)

Create a new path object of the same type by combining the given *pathsegments*. This method is called whenever a derivative path is created, such as from *parent* and *relative_to()*. Subclasses may override this method to pass information to derivative paths, for example:

```
from pathlib import PurePosixPath

class MyPath(PurePosixPath):
    def __init__(self, *pathsegments, session_id):
        super().__init__(*pathsegments)
        self.session_id = session_id

    def with_segments(self, *pathsegments):
        return type(self)(*pathsegments, session_id=self.session_id)

etc = MyPath('/etc', session_id=42)
hosts = etc / 'hosts'
print(hosts.session_id)  # 42
```

Added in version 3.12.

11.1.4 Concrete paths

Concrete paths are subclasses of the pure path classes. In addition to operations provided by the latter, they also provide methods to do system calls on path objects. There are three ways to instantiate concrete paths:

class pathlib.**Path**(**pathsegments*)

A subclass of *PurePath*, this class represents concrete paths of the system's path flavour (instantiating it creates either a *PosixPath* or a *WindowsPath*):

```
>>> Path('setup.py')
PosixPath('setup.py')
```

pathsegments is specified similarly to *PurePath*.

class pathlib.**PosixPath**(**pathsegments*)

A subclass of *Path* and *PurePosixPath*, this class represents concrete non-Windows filesystem paths:

```
>>> PosixPath('/etc/hosts')
PosixPath('/etc/hosts')
```

pathsegments is specified similarly to *PurePath*.

Changed in version 3.13: Raises *UnsupportedOperation* on Windows. In previous versions, *NotImplementedError* was raised instead.

class pathlib.**WindowsPath**(**pathsegments*)

A subclass of *Path* and *PureWindowsPath*, this class represents concrete Windows filesystem paths:

```
>>> WindowsPath('c:/', 'Users', 'Ximénez')
WindowsPath('c:/Users/Ximénez')
```

pathsegments is specified similarly to *PurePath*.

Changed in version 3.13: Raises *UnsupportedOperation* on non-Windows platforms. In previous versions, *NotImplementedError* was raised instead.

You can only instantiate the class flavour that corresponds to your system (allowing system calls on non-compatible path flavours could lead to bugs or failures in your application):

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 798, in __new__
    % (cls.__name__,))
UnsupportedOperation: cannot instantiate 'WindowsPath' on your system
```

Some concrete path methods can raise an *OSError* if a system call fails (for example because the path doesn't exist).

Parsing and generating URIs

Concrete path objects can be created from, and represented as, 'file' URIs conforming to **RFC 8089**.

Note

File URIs are not portable across machines with different *filesystem encodings*.

classmethod Path.**from_uri**(*uri*)

Return a new path object from parsing a 'file' URI. For example:

```
>>> p = Path.from_uri('file:///etc/hosts')
PosixPath('/etc/hosts')
```

On Windows, DOS device and UNC paths may be parsed from URIs:

```
>>> p = Path.from_uri('file:///c:/windows')
WindowsPath('c:/windows')
>>> p = Path.from_uri('file://server/share')
WindowsPath('//server/share')
```

Several variant forms are supported:

```
>>> p = Path.from_uri('file:////server/share')
WindowsPath('//server/share')
>>> p = Path.from_uri('file://///server/share')
WindowsPath('//server/share')
>>> p = Path.from_uri('file:c:/windows')
```

(continues on next page)

(continued from previous page)

```
WindowsPath('c:/windows')
>>> p = Path.from_uri('file:/c|/windows')
WindowsPath('c:/windows')
```

ValueError is raised if the URI does not start with `file:`, or the parsed path isn't absolute.

Added in version 3.13.

`Path.`**`as_uri`**`()`

Represent the path as a 'file' URI. *ValueError* is raised if the path isn't absolute.

```
>>> p = PosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = WindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

For historical reasons, this method is also available from *PurePath* objects. However, its use of *os.fsencode()* makes it strictly impure.

Expanding and resolving paths

`classmethod` `Path.`**`home`**`()`

Return a new path object representing the user's home directory (as returned by *os.path.expanduser()* with ~ construct). If the home directory can't be resolved, *RuntimeError* is raised.

```
>>> Path.home()
PosixPath('/home/antoine')
```

Added in version 3.5.

`Path.`**`expanduser`**`()`

Return a new path with expanded ~ and `~user` constructs, as returned by *os.path.expanduser()*. If a home directory can't be resolved, *RuntimeError* is raised.

```
>>> p = PosixPath('~/films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/films/Monty Python')
```

Added in version 3.5.

`classmethod` `Path.`**`cwd`**`()`

Return a new path object representing the current directory (as returned by *os.getcwd()*):

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

`Path.`**`absolute`**`()`

Make the path absolute, without normalization or resolving symlinks. Returns a new path object:

```
>>> p = Path('tests')
>>> p
PosixPath('tests')
>>> p.absolute()
PosixPath('/home/antoine/pathlib/tests')
```

Path.**resolve**(*strict=False*)

Make the path absolute, resolving any symlinks. A new path object is returned:

```
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

"`..`" components are also eliminated (this is the only method to do so):

```
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

If a path doesn't exist or a symlink loop is encountered, and *strict* is `True`, *OSError* is raised. If *strict* is `False`, the path is resolved as far as possible and any remainder is appended without checking whether it exists.

Changed in version 3.6: The *strict* parameter was added (pre-3.6 behavior is strict).

Changed in version 3.13: Symlink loops are treated like other errors: *OSError* is raised in strict mode, and no exception is raised in non-strict mode. In previous versions, *RuntimeError* is raised no matter the value of *strict*.

Path.**readlink**()

Return the path to which the symbolic link points (as returned by *os.readlink()*):

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.readlink()
PosixPath('setup.py')
```

Added in version 3.9.

Changed in version 3.13: Raises *UnsupportedOperation* if *os.readlink()* is not available. In previous versions, *NotImplementedError* was raised.

Querying file type and status

Changed in version 3.8: *exists()*, *is_dir()*, *is_file()*, *is_mount()*, *is_symlink()*, *is_block_device()*, *is_char_device()*, *is_fifo()*, *is_socket()* now return `False` instead of raising an exception for paths that contain characters unrepresentable at the OS level.

Path.**stat**(*, *follow_symlinks=True*)

Return an *os.stat_result* object containing information about this path, like *os.stat()*. The result is looked up at each call to this method.

This method normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use *lstat()*.

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

Changed in version 3.10: The *follow_symlinks* parameter was added.

Path.**lstat**()

Like *Path.stat()* but, if the path points to a symbolic link, return the symbolic link's information rather than its target's.

Path.**exists**(*, *follow_symlinks=True*)

Return `True` if the path points to an existing file or directory.

This method normally follows symlinks; to check if a symlink exists, add the argument `follow_symlinks=False`.

```
>>> Path('.').exists()
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False
```

Changed in version 3.12: The *follow_symlinks* parameter was added.

Path.**is_file**(*, *follow_symlinks=True*)

Return `True` if the path points to a regular file, `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

This method normally follows symlinks; to exclude symlinks, add the argument `follow_symlinks=False`.

Changed in version 3.13: The *follow_symlinks* parameter was added.

Path.**is_dir**(*, *follow_symlinks=True*)

Return `True` if the path points to a directory, `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

This method normally follows symlinks; to exclude symlinks to directories, add the argument `follow_symlinks=False`.

Changed in version 3.13: The *follow_symlinks* parameter was added.

Path.**is_symlink**()

Return `True` if the path points to a symbolic link, `False` otherwise.

`False` is also returned if the path doesn't exist; other errors (such as permission errors) are propagated.

Path.**is_junction**()

Return `True` if the path points to a junction, and `False` for any other type of file. Currently only Windows supports junctions.

Added in version 3.12.

Path.**is_mount**()

Return `True` if the path is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, `path/..`, is on a different device than *path*, or whether `path/..` and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. On Windows, a mount point is considered to be a drive letter root (e.g. `c:\`), a UNC share (e.g. `\\server\share`), or a mounted filesystem directory.

Added in version 3.7.

Changed in version 3.12: Windows support was added.

Path.**is_socket**()

Return `True` if the path points to a Unix socket (or a symbolic link pointing to a Unix socket), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Path.**is_fifo**()

Return `True` if the path points to a FIFO (or a symbolic link pointing to a FIFO), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Path.**is_block_device**()

Return `True` if the path points to a block device (or a symbolic link pointing to a block device), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Path.**is_char_device**()

Return `True` if the path points to a character device (or a symbolic link pointing to a character device), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Path.**samefile**(*other_path*)

Return whether this path points to the same file as *other_path*, which can be either a Path object, or a string. The semantics are similar to *os.path.samefile()* and *os.path.samestat()*.

An *OSError* can be raised if either file cannot be accessed for some reason.

```
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

Added in version 3.5.

Reading and writing files

Path.**open**(*mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*)

Open the file pointed to by the path, like the built-in *open()* function does:

```
>>> p = Path('setup.py')
>>> with p.open() as f:
...     f.readline()
...
'#!/usr/bin/env python3\n'
```

Path.**read_text**(*encoding=None*, *errors=None*, *newline=None*)

Return the decoded contents of the pointed-to file as a string:

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

The file is opened and then closed. The optional parameters have the same meaning as in *open()*.

Added in version 3.5.

Changed in version 3.13: The *newline* parameter was added.

Path.**read_bytes**()

Return the binary contents of the pointed-to file as a bytes object:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

Added in version 3.5.

Path.**write_text**(*data*, *encoding=None*, *errors=None*, *newline=None*)

Open the file pointed to in text mode, write *data* to it, and close the file:

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

An existing file of the same name is overwritten. The optional parameters have the same meaning as in *open()*.

Added in version 3.5.

Changed in version 3.10: The *newline* parameter was added.

Path.**write_bytes**(*data*)

Open the file pointed to in bytes mode, write *data* to it, and close the file:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

An existing file of the same name is overwritten.

Added in version 3.5.

Reading directories

Path.**iterdir**()

When the path points to a directory, yield path objects of the directory contents:

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...
PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/Makefile')
```

The children are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, it is unspecified whether a path object for that file is included.

If the path is not a directory or otherwise inaccessible, *OSError* is raised.

Path.**glob**(*pattern*, *, *case_sensitive=None*, *recurse_symlinks=False*)

Glob the given relative *pattern* in the directory represented by this path, yielding all matching files (of any kind):

```
>>> sorted(Path('.').glob('*.py'))
[PosixPath('pathlib.py'), PosixPath('setup.py'), PosixPath('test_pathlib.py')]
>>> sorted(Path('.').glob('*/*.py'))
[PosixPath('docs/conf.py')]
>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

See also

Pattern language documentation.

By default, or when the *case_sensitive* keyword-only argument is set to `None`, this method matches paths using platform-specific casing rules: typically, case-sensitive on POSIX, and case-insensitive on Windows. Set *case_sensitive* to `True` or `False` to override this behaviour.

By default, or when the *recurse_symlinks* keyword-only argument is set to `False`, this method follows symlinks except when expanding "`**`" wildcards. Set *recurse_symlinks* to `True` to always follow symlinks.

Raises an *auditing event* `pathlib.Path.glob` with arguments `self`, `pattern`.

Changed in version 3.12: The *case_sensitive* parameter was added.

Changed in version 3.13: The *recurse_symlinks* parameter was added.

Changed in version 3.13: The *pattern* parameter accepts a *path-like object*.

Changed in version 3.13: Any *OSError* exceptions raised from scanning the filesystem are suppressed. In previous versions, such exceptions are suppressed in many cases, but not all.

Path.**rglob**(*pattern*, *, *case_sensitive=None*, *recurse_symlinks=False*)

Glob the given relative *pattern* recursively. This is like calling *Path.glob()* with "`**/`" added in front of the *pattern*.

See also

Pattern language and *Path.glob()* documentation.

Raises an *auditing event* `pathlib.Path.rglob` with arguments `self`, `pattern`.

Changed in version 3.12: The *case_sensitive* parameter was added.

Changed in version 3.13: The *recurse_symlinks* parameter was added.

Changed in version 3.13: The *pattern* parameter accepts a *path-like object*.

Path.**walk**(*top_down=True*, *on_error=None*, *follow_symlinks=False*)

Generate the file names in a directory tree by walking the tree either top-down or bottom-up.

For each directory in the directory tree rooted at *self* (including *self* but excluding '.' and '..'), the method yields a 3-tuple of `(dirpath, dirnames, filenames)`.

dirpath is a *Path* to the directory currently being walked, *dirnames* is a list of strings for the names of subdirectories in *dirpath* (excluding `'.'` and `'..'`), and *filenames* is a list of strings for the names of the non-directory

files in *dirpath*. To get a full path (which begins with *self*) to a file or directory in *dirpath*, do `dirpath / name`. Whether or not the lists are sorted is file system-dependent.

If the optional argument *top_down* is true (which is the default), the triple for a directory is generated before the triples for any of its subdirectories (directories are walked top-down). If *top_down* is false, the triple for a directory is generated after the triples for all of its subdirectories (directories are walked bottom-up). No matter the value of *top_down*, the list of subdirectories is retrieved before the triples for the directory and its subdirectories are walked.

When *top_down* is true, the caller can modify the *dirnames* list in-place (for example, using `del` or slice assignment), and *Path.walk()* will only recurse into the subdirectories whose names remain in *dirnames*. This can be used to prune the search, or to impose a specific order of visiting, or even to inform *Path.walk()* about directories the caller creates or renames before it resumes *Path.walk()* again. Modifying *dirnames* when *top_down* is false has no effect on the behavior of *Path.walk()* since the directories in *dirnames* have already been generated by the time *dirnames* is yielded to the caller.

By default, errors from *os.scandir()* are ignored. If the optional argument *on_error* is specified, it should be a callable; it will be called with one argument, an *OSError* instance. The callable can handle the error to continue the walk or re-raise it to stop the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, *Path.walk()* does not follow symbolic links, and instead adds them to the *filenames* list. Set *follow_symlinks* to true to resolve symlinks and place them in *dirnames* and *filenames* as appropriate for their targets, and consequently visit directories pointed to by symlinks (where supported).

Note

Be aware that setting *follow_symlinks* to true can lead to infinite recursion if a link points to a parent directory of itself. *Path.walk()* does not keep track of the directories it has already visited.

Note

Path.walk() assumes the directories it walks are not modified during execution. For example, if a directory from *dirnames* has been replaced with a symlink and *follow_symlinks* is false, *Path.walk()* will still try to descend into it. To prevent such behavior, remove directories from *dirnames* as appropriate.

Note

Unlike *os.walk()*, *Path.walk()* lists symlinks to directories in *filenames* if *follow_symlinks* is false.

This example displays the number of bytes used by all files in each directory, while ignoring `__pycache__` directories:

```
from pathlib import Path
for root, dirs, files in Path("cpython/Lib/concurrent").walk(on_error=print):
  print(
      root,
      "consumes",
      sum((root / file).stat().st_size for file in files),
      "bytes in",
      len(files),
      "non-directory files"
  )
  if '__pycache__' in dirs:
        dirs.remove('__pycache__')
```

This next example is a simple implementation of *shutil.rmtree()*. Walking the tree bottom-up is essential as *rmdir()* doesn't allow deleting a directory before it is empty:

```
# Delete everything reachable from the directory "top".
# CAUTION:  This is dangerous! For example, if top == Path('/'),
# it could delete all of your files.
for root, dirs, files in top.walk(top_down=False):
    for name in files:
        (root / name).unlink()
    for name in dirs:
        (root / name).rmdir()
```

Added in version 3.12.

Creating files and directories

`Path.`**`touch`**(*mode=0o666*, *exist_ok=True*)

Create a file at this given path. If *mode* is given, it is combined with the process's `umask` value to determine the file mode and access flags. If the file already exists, the function succeeds when *exist_ok* is true (and its modification time is updated to the current time), otherwise *FileExistsError* is raised.

See also

The *open()*, *write_text()* and *write_bytes()* methods are often used to create files.

`Path.`**`mkdir`**(*mode=0o777*, *parents=False*, *exist_ok=False*)

Create a new directory at this given path. If *mode* is given, it is combined with the process's `umask` value to determine the file mode and access flags. If the path already exists, *FileExistsError* is raised.

If *parents* is true, any missing parents of this path are created as needed; they are created with the default permissions without taking *mode* into account (mimicking the POSIX `mkdir -p` command).

If *parents* is false (the default), a missing parent raises *FileNotFoundError*.

If *exist_ok* is false (the default), *FileExistsError* is raised if the target directory already exists.

If *exist_ok* is true, *FileExistsError* will not be raised unless the given path already exists in the file system and is not a directory (same behavior as the POSIX `mkdir -p` command).

Changed in version 3.5: The *exist_ok* parameter was added.

`Path.`**`symlink_to`**(*target*, *target_is_directory=False*)

Make this path a symbolic link pointing to *target*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target_is_directory* is true or a file symlink (the default) otherwise. On non-Windows platforms, *target_is_directory* is ignored.

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

> **Note**
>
> The order of arguments (link, target) is the reverse of *os.symlink()*'s.

Changed in version 3.13: Raises *UnsupportedOperation* if *os.symlink()* is not available. In previous versions, *NotImplementedError* was raised.

`Path.`**`hardlink_to`**(*target*)

Make this path a hard link to the same file as *target*.

> **Note**
>
> The order of arguments (link, target) is the reverse of *os.link()*'s.

Added in version 3.10.

Changed in version 3.13: Raises *UnsupportedOperation* if *os.link()* is not available. In previous versions, *NotImplementedError* was raised.

Renaming and deleting

`Path.`**`rename`**(*target*)

Rename this file or directory to the given *target*, and return a new `Path` instance pointing to *target*. On Unix, if *target* exists and is a file, it will be replaced silently if the user has permission. On Windows, if *target* exists, *FileExistsError* will be raised. *target* can be either a string or another path object:

```
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
PosixPath('bar')
>>> target.open().read()
'some text'
```

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the `Path` object.

It is implemented in terms of *os.rename()* and gives the same guarantees.

Changed in version 3.8: Added return value, return the new `Path` instance.

`Path.`**`replace`**(*target*)

Rename this file or directory to the given *target*, and return a new `Path` instance pointing to *target*. If *target* points to an existing file or empty directory, it will be unconditionally replaced.

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the `Path` object.

Changed in version 3.8: Added return value, return the new `Path` instance.

`Path.`**`unlink`**(*missing_ok=False*)

Remove this file or symbolic link. If the path points to a directory, use *Path.rmdir()* instead.

If *missing_ok* is false (the default), *FileNotFoundError* is raised if the path does not exist.

If *missing_ok* is true, *FileNotFoundError* exceptions will be ignored (same behavior as the POSIX `rm -f` command).

Changed in version 3.8: The *missing_ok* parameter was added.

Path.**rmdir**()

Remove this directory. The directory must be empty.

Permissions and ownership

Path.**owner**(*, *follow_symlinks=True*)

Return the name of the user owning the file. *KeyError* is raised if the file's user identifier (UID) isn't found in the system database.

This method normally follows symlinks; to get the owner of the symlink, add the argument `follow_symlinks=False`.

Changed in version 3.13: Raises *UnsupportedOperation* if the *pwd* module is not available. In earlier versions, *NotImplementedError* was raised.

Changed in version 3.13: The *follow_symlinks* parameter was added.

Path.**group**(*, *follow_symlinks=True*)

Return the name of the group owning the file. *KeyError* is raised if the file's group identifier (GID) isn't found in the system database.

This method normally follows symlinks; to get the group of the symlink, add the argument `follow_symlinks=False`.

Changed in version 3.13: Raises *UnsupportedOperation* if the *grp* module is not available. In earlier versions, *NotImplementedError* was raised.

Changed in version 3.13: The *follow_symlinks* parameter was added.

Path.**chmod**(*mode*, *, *follow_symlinks=True*)

Change the file mode and permissions, like *os.chmod()*.

This method normally follows symlinks. Some Unix flavours support changing permissions on the symlink itself; on these platforms you may add the argument `follow_symlinks=False`, or use *lchmod()*.

```
>>> p = Path('setup.py')
>>> p.stat().st_mode
33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060
```

Changed in version 3.10: The *follow_symlinks* parameter was added.

Path.**lchmod**(*mode*)

Like *Path.chmod()* but, if the path points to a symbolic link, the symbolic link's mode is changed rather than its target's.

11.1.5 Pattern language

The following wildcards are supported in patterns for *full_match()*, *glob()* and *rglob()*:

**** (entire segment)**
Matches any number of file or directory segments, including zero.

*** (entire segment)**
Matches one file or directory segment.

*** (part of a segment)**
Matches any number of non-separator characters, including zero.

?
Matches one non-separator character.

[seq]
Matches one character in *seq*, where *seq* is a sequence of characters. Range expressions are supported; for example, `[a-z]` matches any lowercase ASCII letter. Multiple ranges can be combined: `[a-zA-Z0-9_]` matches any ASCII letter, digit, or underscore.

[!seq]
Matches one character not in *seq*, where *seq* follows the same rules as above.

For a literal match, wrap the meta-characters in brackets. For example, `"[?]"` matches the character `"?"`.

The "`**`" wildcard enables recursive globbing. A few examples:

Pattern	Meaning
"`**/*`"	Any path with at least one segment.
"`**/*.py`"	Any path with a final segment ending "`.py`".
"`assets/**`"	Any path starting with "`assets/`".
"`assets/**/*`"	Any path starting with "`assets/`", excluding "`assets/`" itself.

Note

Globbing with the "`**`" wildcard visits every directory in the tree. Large directory trees may take a long time to search.

Changed in version 3.13: Globbing with a pattern that ends with "`**`" returns both files and directories. In previous versions, only directories were returned.

In *`Path.glob()`* and *`rglob()`*, a trailing slash may be added to the pattern to match only directories.

Changed in version 3.11: Globbing with a pattern that ends with a pathname components separator (*`sep`* or *`altsep`*) returns only directories.

11.1.6 Comparison to the `glob` module

The patterns accepted and results generated by *`Path.glob()`* and *`Path.rglob()`* differ slightly from those by the *`glob`* module:

1. Files beginning with a dot are not special in pathlib. This is like passing `include_hidden=True` to *`glob.glob()`*.
2. "`**`" pattern components are always recursive in pathlib. This is like passing `recursive=True` to *`glob.glob()`*.
3. "`**`" pattern components do not follow symlinks by default in pathlib. This behaviour has no equivalent in *`glob.glob()`*, but you can pass `recurse_symlinks=True` to *`Path.glob()`* for compatible behaviour.
4. Like all *`PurePath`* and *`Path`* objects, the values returned from *`Path.glob()`* and *`Path.rglob()`* don't include trailing slashes.
5. The values returned from pathlib's `path.glob()` and `path.rglob()` include the *path* as a prefix, unlike the results of `glob.glob(root_dir=path)`.
6. The values returned from pathlib's `path.glob()` and `path.rglob()` may include *path* itself, for example when globbing "`**`", whereas the results of `glob.glob(root_dir=path)` never include an empty string that would correspond to *path*.

11.1.7 Comparison to the `os` and `os.path` modules

pathlib implements path operations using *`PurePath`* and *`Path`* objects, and so it's said to be *object-oriented*. On the other hand, the *`os`* and *`os.path`* modules supply functions that work with low-level `str` and `bytes` objects, which is a more *procedural* approach. Some users consider the object-oriented style to be more readable.

Many functions in *os* and *os.path* support `bytes` paths and *paths relative to directory descriptors*. These features aren't available in pathlib.

Python's `str` and `bytes` types, and portions of the *os* and *os.path* modules, are written in C and are very speedy. pathlib is written in pure Python and is often slower, but rarely slow enough to matter.

pathlib's path normalization is slightly more opinionated and consistent than *os.path*. For example, whereas *os.path.abspath()* eliminates "`..`" segments from a path, which may change its meaning if symlinks are involved, *Path.absolute()* preserves these segments for greater safety.

pathlib's path normalization may render it unsuitable for some applications:

1. pathlib normalizes `Path("my_folder/")` to `Path("my_folder")`, which changes a path's meaning when supplied to various operating system APIs and command-line utilities. Specifically, the absence of a trailing separator may allow the path to be resolved as either a file or directory, rather than a directory only.
2. pathlib normalizes `Path("./my_program")` to `Path("my_program")`, which changes a path's meaning when used as an executable search path, such as in a shell or when spawning a child process. Specifically, the absence of a separator in the path may force it to be looked up in `PATH` rather than the current directory.

As a consequence of these differences, pathlib is not a drop-in replacement for *os.path*.

Corresponding tools

Below is a table mapping various *os* functions to their corresponding *PurePath*/*Path* equivalent.

os and *os.path*	*pathlib*
os.path.dirname()	*PurePath.parent*
os.path.basename()	*PurePath.name*
os.path.splitext()	*PurePath.stem*, *PurePath.suffix*
os.path.join()	*PurePath.joinpath()*
os.path.isabs()	*PurePath.is_absolute()*
os.path.relpath()	*PurePath.relative_to()*[1]
os.path.expanduser()	*Path.expanduser()*[2]
os.path.realpath()	*Path.resolve()*
os.path.abspath()	*Path.absolute()*[3]
os.path.exists()	*Path.exists()*
os.path.isfile()	*Path.is_file()*
os.path.isdir()	*Path.is_dir()*
os.path.islink()	*Path.is_symlink()*
os.path.isjunction()	*Path.is_junction()*
os.path.ismount()	*Path.is_mount()*
os.path.samefile()	*Path.samefile()*
os.getcwd()	*Path.cwd()*
os.stat()	*Path.stat()*
os.lstat()	*Path.lstat()*
os.listdir()	*Path.iterdir()*
os.walk()	*Path.walk()*[4]
os.mkdir(), *os.makedirs()*	*Path.mkdir()*
os.link()	*Path.hardlink_to()*
os.symlink()	*Path.symlink_to()*
os.readlink()	*Path.readlink()*
os.rename()	*Path.rename()*
os.replace()	*Path.replace()*
os.remove(), *os.unlink()*	*Path.unlink()*
os.rmdir()	*Path.rmdir()*
os.chmod()	*Path.chmod()*
os.lchmod()	*Path.lchmod()*

11.2 os.path — Common pathname manipulations

Source code: Lib/genericpath.py, Lib/posixpath.py (for POSIX) and Lib/ntpath.py (for Windows).

This module implements some useful functions on pathnames. To read or write files see *open()*, and for accessing the filesystem see the *os* module. The path parameters can be passed as strings, or bytes, or any object implementing the *os.PathLike* protocol.

Unlike a Unix shell, Python does not do any *automatic* path expansions. Functions such as *expanduser()* and *expandvars()* can be invoked explicitly when an application desires shell-like path expansion. (See also the *glob* module.)

See also

The *pathlib* module offers high-level path objects.

Note

All of these functions accept either only bytes or only string objects as their parameters. The result is an object of the same type, if a path or file name is returned.

Note

Since different operating systems have different path name conventions, there are several versions of this module in the standard library. The *os.path* module is always the path module suitable for the operating system Python is running on, and therefore usable for local paths. However, you can also import and use the individual modules if you want to manipulate a path that is *always* in one of the different formats. They all have the same interface:

- `posixpath` for UNIX-style paths
- `ntpath` for Windows paths

Changed in version 3.8: *exists()*, *lexists()*, *isdir()*, *isfile()*, *islink()*, and *ismount()* now return `False` instead of raising an exception for paths that contain characters or bytes unrepresentable at the OS level.

`os.path.`**`abspath`**(*path*)

Return a normalized absolutized version of the pathname *path*. On most platforms, this is equivalent to calling the function *normpath()* as follows: `normpath(join(os.getcwd(), path))`.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`basename`**(*path*)

Return the base name of pathname *path*. This is the second element of the pair returned by passing *path* to the function *split()*. Note that the result of this function is different from the Unix **basename** program; where **basename** for `'/foo/bar/'` returns `'bar'`, the *basename()* function returns an empty string (`''`).

[1] *os.path.relpath()* calls *abspath()* to make paths absolute and remove "." parts, whereas *PurePath.relative_to()* is a lexical operation that raises *ValueError* when its inputs' anchors differ (e.g. if one path is absolute and the other relative.)

[2] *os.path.expanduser()* returns the path unchanged if the home directory can't be resolved, whereas *Path.expanduser()* raises *RuntimeError*.

[3] *os.path.abspath()* removes "." components without resolving symlinks, which may change the meaning of the path, whereas *Path.absolute()* leaves any "." components in the path.

[4] *os.walk()* always follows symlinks when categorizing paths into *dirnames* and *filenames*, whereas *Path.walk()* categorizes all symlinks into *filenames* when *follow_symlinks* is false (the default.)

Changed in version 3.6: Accepts a *path-like object*.

os.path.**commonpath**(*paths*)

Return the longest common sub-path of each pathname in the iterable *paths*. Raise `ValueError` if *paths* contain both absolute and relative pathnames, if *paths* are on different drives, or if *paths* is empty. Unlike `commonprefix()`, this returns a valid path.

Added in version 3.5.

Changed in version 3.6: Accepts a sequence of *path-like objects*.

Changed in version 3.13: Any iterable can now be passed, rather than just sequences.

os.path.**commonprefix**(*list*)

Return the longest path prefix (taken character-by-character) that is a prefix of all paths in *list*. If *list* is empty, return the empty string (`''`).

Note

This function may return invalid paths because it works a character at a time. To obtain a valid path, see `commonpath()`.

```
>>> os.path.commonprefix(['/usr/lib', '/usr/local/lib'])
'/usr/l'

>>> os.path.commonpath(['/usr/lib', '/usr/local/lib'])
'/usr'
```

Changed in version 3.6: Accepts a *path-like object*.

os.path.**dirname**(*path*)

Return the directory name of pathname *path*. This is the first element of the pair returned by passing *path* to the function `split()`.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**exists**(*path*)

Return `True` if *path* refers to an existing path or an open file descriptor. Returns `False` for broken symbolic links. On some platforms, this function may return `False` if permission is not granted to execute `os.stat()` on the requested file, even if the *path* physically exists.

Changed in version 3.3: *path* can now be an integer: `True` is returned if it is an open file descriptor, `False` otherwise.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**lexists**(*path*)

Return `True` if *path* refers to an existing path, including broken symbolic links. Equivalent to `exists()` on platforms lacking `os.lstat()`.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**expanduser**(*path*)

On Unix and Windows, return the argument with an initial component of `~` or `~user` replaced by that *user*'s home directory.

On Unix, an initial `~` is replaced by the environment variable `HOME` if it is set; otherwise the current user's home directory is looked up in the password directory through the built-in module `pwd`. An initial `~user` is looked up directly in the password directory.

On Windows, `USERPROFILE` will be used if set, otherwise a combination of `HOMEPATH` and `HOMEDRIVE` will be used. An initial `~user` is handled by checking that the last directory component of the current user's home directory matches `USERNAME`, and replacing it if so.

If the expansion fails or if the path does not begin with a tilde, the path is returned unchanged.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.8: No longer uses `HOME` on Windows.

`os.path.`**`expandvars`**(*path*)

Return the argument with environment variables expanded. Substrings of the form `$name` or `${name}` are replaced by the value of environment variable *name*. Malformed variable names and references to non-existing variables are left unchanged.

On Windows, `%name%` expansions are supported in addition to `$name` and `${name}`.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`getatime`**(*path*)

Return the time of last access of *path*. The return value is a floating-point number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

`os.path.`**`getmtime`**(*path*)

Return the time of last modification of *path*. The return value is a floating-point number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`getctime`**(*path*)

Return the system's ctime which, on some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time for *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`getsize`**(*path*)

Return the size, in bytes, of *path*. Raise *OSError* if the file does not exist or is inaccessible.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`isabs`**(*path*)

Return `True` if *path* is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with two (back)slashes, or a drive letter, colon, and (back)slash together.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.13: On Windows, returns `False` if the given path starts with exactly one (back)slash.

`os.path.`**`isfile`**(*path*)

Return `True` if *path* is an *existing* regular file. This follows symbolic links, so both *islink()* and *isfile()* can be true for the same path.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`isdir`**(*path*)

Return `True` if *path* is an *existing* directory. This follows symbolic links, so both *islink()* and *isdir()* can be true for the same path.

Changed in version 3.6: Accepts a *path-like object*.

`os.path.`**`isjunction`**(*path*)

Return `True` if *path* refers to an *existing* directory entry that is a junction. Always return `False` if junctions are not supported on the current platform.

Added in version 3.12.

`os.path.`**`islink`**(*path*)

Return `True` if *path* refers to an *existing* directory entry that is a symbolic link. Always `False` if symbolic links are not supported by the Python runtime.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**ismount**(*path*)

Return `True` if pathname *path* is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, `path/..`, is on a different device than *path*, or whether `path/..` and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. It is not able to reliably detect bind mounts on the same filesystem. On Windows, a drive letter root and a share UNC are always mount points, and for any other path `GetVolumePathName` is called to see if it is different from the input path.

Changed in version 3.4: Added support for detecting non-root mount points on Windows.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**isdevdrive**(*path*)

Return `True` if pathname *path* is located on a Windows Dev Drive. A Dev Drive is optimized for developer scenarios, and offers faster performance for reading and writing files. It is recommended for use for source code, temporary build directories, package caches, and other IO-intensive operations.

May raise an error for an invalid path, for example, one without a recognizable drive, but returns `False` on platforms that do not support Dev Drives. See the Windows documentation for information on enabling and creating Dev Drives.

Added in version 3.12.

Changed in version 3.13: The function is now available on all platforms, and will always return `False` on those that have no support for Dev Drives

os.path.**isreserved**(*path*)

Return `True` if *path* is a reserved pathname on the current system.

On Windows, reserved filenames include those that end with a space or dot; those that contain colons (i.e. file streams such as "name:stream"), wildcard characters (i.e. `'*?"<>'`), pipe, or ASCII control characters; as well as DOS device names such as "NUL", "CON", "CONIN$", "CONOUT$", "AUX", "PRN", "COM1", and "LPT1".

> **Note**
>
> This function approximates rules for reserved paths on most Windows systems. These rules change over time in various Windows releases. This function may be updated in future Python releases as changes to the rules become broadly available.

Availability: Windows.

Added in version 3.13.

os.path.**join**(*path*, **paths*)

Join one or more path segments intelligently. The return value is the concatenation of *path* and all members of **paths*, with exactly one directory separator following each non-empty part, except the last. That is, the result will only end in a separator if the last part is either empty or ends in a separator. If a segment is an absolute path (which on Windows requires both a drive and a root), then all previous segments are ignored and joining continues from the absolute path segment.

On Windows, the drive is not reset when a rooted path segment (e.g., `r'\foo'`) is encountered. If a segment is on a different drive or is an absolute path, all previous segments are ignored and the drive is reset. Note that since there is a current directory for each drive, `os.path.join("c:", "foo")` represents a path relative to the current directory on drive `C:` (`c:foo`), not `c:\foo`.

Changed in version 3.6: Accepts a *path-like object* for *path* and *paths*.

os.path.**normcase**(*path*)

Normalize the case of a pathname. On Windows, convert all characters in the pathname to lowercase, and also convert forward slashes to backward slashes. On other operating systems, return the path unchanged.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**normpath**(*path*)

Normalize a pathname by collapsing redundant separators and up-level references so that `A//B`, `A/B/`, `A/./B` and `A/foo/../B` all become `A/B`. This string manipulation may change the meaning of a path that contains symbolic links. On Windows, it converts forward slashes to backward slashes. To normalize case, use *normcase()*.

> **Note**
>
> On POSIX systems, in accordance with IEEE Std 1003.1 2013 Edition; 4.13 Pathname Resolution, if a pathname begins with exactly two slashes, the first component following the leading characters may be interpreted in an implementation-defined manner, although more than two leading characters shall be treated as a single character.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**realpath**(*path*, *, *strict=False*)

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system). On Windows, this function will also resolve MS-DOS (also called 8.3) style names such as `C:\\PROGRA~1` to `C:\\Program Files`.

By default, the path is evaluated up to the first component that does not exist, is a symlink loop, or whose evaluation raises *OSError*. All such components are appended unchanged to the existing part of the path.

Some errors that are handled this way include "access denied", "not a directory", or "bad argument to internal function". Thus, the resulting path may be missing or inaccessible, may still contain links or loops, and may traverse non-directories.

This behavior can be modified by keyword arguments:

If *strict* is `True`, the first error encountered when evaluating the path is re-raised. In particular, *FileNotFoundError* is raised if *path* does not exist, or another *OSError* if it is otherwise inaccessible.

If *strict* is *os.path.ALLOW_MISSING*, errors other than *FileNotFoundError* are re-raised (as with `strict=True`). Thus, the returned path will not contain any symbolic links, but the named file and some of its parent directories may be missing.

> **Note**
>
> This function emulates the operating system's procedure for making a path canonical, which differs slightly between Windows and UNIX with respect to how links and subsequent path components interact.
>
> Operating system APIs make paths canonical as needed, so it's not normally necessary to call this function.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.8: Symbolic links and junctions are now resolved on Windows.

Changed in version 3.10: The *strict* parameter was added.

Changed in version 3.13.4: The *ALLOW_MISSING* value for the *strict* parameter was added.

os.path.**ALLOW_MISSING**

Special value used for the *strict* argument in *realpath()*.

Added in version 3.13.4.

os.path.**relpath**(*path*, *start=os.curdir*)

Return a relative filepath to *path* either from the current directory or from an optional *start* directory. This is a path computation: the filesystem is not accessed to confirm the existence or nature of *path* or *start*. On Windows, *ValueError* is raised when *path* and *start* are on different drives.

start defaults to *os.curdir*.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**samefile**(*path1*, *path2*)

Return `True` if both pathname arguments refer to the same file or directory. This is determined by the device number and i-node number and raises an exception if an `os.stat()` call on either pathname fails.

Changed in version 3.2: Added Windows support.

Changed in version 3.4: Windows now uses the same implementation as all other platforms.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**sameopenfile**(*fp1*, *fp2*)

Return `True` if the file descriptors *fp1* and *fp2* refer to the same file.

Changed in version 3.2: Added Windows support.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**samestat**(*stat1*, *stat2*)

Return `True` if the stat tuples *stat1* and *stat2* refer to the same file. These structures may have been returned by `os.fstat()`, `os.lstat()`, or `os.stat()`. This function implements the underlying comparison used by `samefile()` and `sameopenfile()`.

Changed in version 3.4: Added Windows support.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**split**(*path*)

Split the pathname *path* into a pair, `(head, tail)` where *tail* is the last pathname component and *head* is everything leading up to that. The *tail* part will never contain a slash; if *path* ends in a slash, *tail* will be empty. If there is no slash in *path*, *head* will be empty. If *path* is empty, both *head* and *tail* are empty. Trailing slashes are stripped from *head* unless it is the root (one or more slashes only). In all cases, `join(head, tail)` returns a path to the same location as *path* (but the strings may differ). Also see the functions `dirname()` and `basename()`.

Changed in version 3.6: Accepts a *path-like object*.

os.path.**splitdrive**(*path*)

Split the pathname *path* into a pair `(drive, tail)` where *drive* is either a mount point or the empty string. On systems which do not use drive specifications, *drive* will always be the empty string. In all cases, `drive + tail` will be the same as *path*.

On Windows, splits a pathname into drive/UNC sharepoint and relative path.

If the path contains a drive letter, drive will contain everything up to and including the colon:

```
>>> splitdrive("c:/dir")
("c:", "/dir")
```

If the path contains a UNC path, drive will contain the host name and share:

```
>>> splitdrive("//host/computer/dir")
("//host/computer", "/dir")
```

Changed in version 3.6: Accepts a *path-like object*.

os.path.**splitroot**(*path*)

Split the pathname *path* into a 3-item tuple `(drive, root, tail)` where *drive* is a device name or mount point, *root* is a string of separators after the drive, and *tail* is everything after the root. Any of these items may be the empty string. In all cases, `drive + root + tail` will be the same as *path*.

On POSIX systems, *drive* is always empty. The *root* may be empty (if *path* is relative), a single forward slash (if *path* is absolute), or two forward slashes (implementation-defined per IEEE Std 1003.1-2017; 4.13 Pathname Resolution.) For example:

```
>>> splitroot('/home/sam')
('', '/', 'home/sam')
>>> splitroot('//home/sam')
('', '//', 'home/sam')
>>> splitroot('///home/sam')
('', '/', '//home/sam')
```

On Windows, *drive* may be empty, a drive-letter name, a UNC share, or a device name. The *root* may be empty, a forward slash, or a backward slash. For example:

```
>>> splitroot('C:/Users/Sam')
('C:', '/', 'Users/Sam')
>>> splitroot('//Server/Share/Users/Sam')
('//Server/Share', '/', 'Users/Sam')
```

Added in version 3.12.

os.path.**splitext**(*path*)

Split the pathname *path* into a pair `(root, ext)` such that `root + ext == path`, and the extension, *ext*, is empty or begins with a period and contains at most one period.

If the path contains no extension, *ext* will be `''`:

```
>>> splitext('bar')
('bar', '')
```

If the path contains an extension, then *ext* will be set to this extension, including the leading period. Note that previous periods will be ignored:

```
>>> splitext('foo.bar.exe')
('foo.bar', '.exe')
>>> splitext('/foo/bar.exe')
('/foo/bar', '.exe')
```

Leading periods of the last component of the path are considered to be part of the root:

```
>>> splitext('.cshrc')
('.cshrc', '')
>>> splitext('/foo/....jpg')
('/foo/....jpg', '')
```

Changed in version 3.6: Accepts a *path-like object*.

os.path.**supports_unicode_filenames**

`True` if arbitrary Unicode strings can be used as file names (within limitations imposed by the file system).

11.3 `stat` — Interpreting `stat()` results

Source code: Lib/stat.py

The *`stat`* module defines constants and functions for interpreting the results of *`os.stat()`*, *`os.fstat()`* and *`os.lstat()`* (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

Changed in version 3.4: The stat module is backed by a C implementation.

The *`stat`* module defines the following functions to test for specific file types:

stat.**S_ISDIR**(*mode*)
Return non-zero if the mode is from a directory.

stat.**S_ISCHR**(*mode*)
Return non-zero if the mode is from a character special device file.

stat.**S_ISBLK**(*mode*)
Return non-zero if the mode is from a block special device file.

stat.**S_ISREG**(*mode*)
Return non-zero if the mode is from a regular file.

stat.**S_ISFIFO**(*mode*)
Return non-zero if the mode is from a FIFO (named pipe).

stat.**S_ISLNK**(*mode*)
Return non-zero if the mode is from a symbolic link.

stat.**S_ISSOCK**(*mode*)
Return non-zero if the mode is from a socket.

stat.**S_ISDOOR**(*mode*)
Return non-zero if the mode is from a door.

Added in version 3.4.

stat.**S_ISPORT**(*mode*)
Return non-zero if the mode is from an event port.

Added in version 3.4.

stat.**S_ISWHT**(*mode*)
Return non-zero if the mode is from a whiteout.

Added in version 3.4.

Two additional functions are defined for more general manipulation of the file's mode:

stat.**S_IMODE**(*mode*)
Return the portion of the file's mode that can be set by *os.chmod()*—that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

stat.**S_IFMT**(*mode*)
Return the portion of the file's mode that describes the file type (used by the `S_IS*()` functions above).

Normally, you would use the `os.path.is*()` functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by *os.path*, like the tests for block and character devices.

Example:

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
       calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.lstat(pathname).st_mode
        if S_ISDIR(mode):
```

(continues on next page)

(continued from previous page)

```
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print('Skipping %s' % pathname)

def visitfile(file):
    print('visiting', file)

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)
```

An additional utility function is provided to convert a file's mode in a human readable string:

stat.**filemode**(*mode*)

Convert a file's mode to a string of the form '-rwxrwxrwx'.

Added in version 3.3.

Changed in version 3.4: The function supports *S_IFDOOR*, *S_IFPORT* and *S_IFWHT*.

All the variables below are simply symbolic indexes into the 10-tuple returned by *os.stat()*, *os.fstat()* or *os.lstat()*.

stat.**ST_MODE**

Inode protection mode.

stat.**ST_INO**

Inode number.

stat.**ST_DEV**

Device inode resides on.

stat.**ST_NLINK**

Number of links to the inode.

stat.**ST_UID**

User id of the owner.

stat.**ST_GID**

Group id of the owner.

stat.**ST_SIZE**

Size in bytes of a plain file; amount of data waiting on some special files.

stat.**ST_ATIME**

Time of last access.

stat.**ST_MTIME**

Time of last modification.

stat.**ST_CTIME**

The "ctime" as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of "file size" changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the "size" is the number of bytes waiting to be read at the time of the call to *os.stat()*, *os.fstat()*, or *os.lstat()*; this can sometimes be

useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the *ST_MODE* field.

Use of the functions above is more portable than use of the first set of flags:

`stat.`**S_IFSOCK**
: Socket.

`stat.`**S_IFLNK**
: Symbolic link.

`stat.`**S_IFREG**
: Regular file.

`stat.`**S_IFBLK**
: Block device.

`stat.`**S_IFDIR**
: Directory.

`stat.`**S_IFCHR**
: Character device.

`stat.`**S_IFIFO**
: FIFO.

`stat.`**S_IFDOOR**
: Door.

  Added in version 3.4.

`stat.`**S_IFPORT**
: Event port.

  Added in version 3.4.

`stat.`**S_IFWHT**
: Whiteout.

  Added in version 3.4.

Note

S_IFDOOR, *S_IFPORT* or *S_IFWHT* are defined as 0 when the platform does not have support for the file types.

The following flags can also be used in the *mode* argument of *os.chmod()*:

`stat.`**S_ISUID**
: Set UID bit.

`stat.`**S_ISGID**
: Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory: files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the *S_ISGID* bit set. For a file that does not have the group execution bit (*S_IXGRP*) set, the set-group-ID bit indicates mandatory file/record locking (see also *S_ENFMT*).

`stat.`**S_ISVTX**
: Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

stat.**S_IRWXU**
Mask for file owner permissions.

stat.**S_IRUSR**
Owner has read permission.

stat.**S_IWUSR**
Owner has write permission.

stat.**S_IXUSR**
Owner has execute permission.

stat.**S_IRWXG**
Mask for group permissions.

stat.**S_IRGRP**
Group has read permission.

stat.**S_IWGRP**
Group has write permission.

stat.**S_IXGRP**
Group has execute permission.

stat.**S_IRWXO**
Mask for permissions for others (not in group).

stat.**S_IROTH**
Others have read permission.

stat.**S_IWOTH**
Others have write permission.

stat.**S_IXOTH**
Others have execute permission.

stat.**S_ENFMT**
System V file locking enforcement. This flag is shared with *S_ISGID*: file/record locking is enforced on files that do not have the group execution bit (*S_IXGRP*) set.

stat.**S_IREAD**
Unix V7 synonym for *S_IRUSR*.

stat.**S_IWRITE**
Unix V7 synonym for *S_IWUSR*.

stat.**S_IEXEC**
Unix V7 synonym for *S_IXUSR*.

The following flags can be used in the *flags* argument of *os.chflags()*:

stat.**UF_SETTABLE**
All user settable flags.

Added in version 3.13.

stat.**UF_NODUMP**
Do not dump the file.

stat.**UF_IMMUTABLE**
The file may not be changed.

stat.**UF_APPEND**
The file may only be appended to.

stat.**UF_OPAQUE**
The directory is opaque when viewed through a union stack.

stat.**UF_NOUNLINK**
The file may not be renamed or deleted.

stat.**UF_COMPRESSED**
The file is stored compressed (macOS 10.6+).

stat.**UF_TRACKED**
Used for handling document IDs (macOS)

Added in version 3.13.

stat.**UF_DATAVAULT**
The file needs an entitlement for reading or writing (macOS 10.13+)

Added in version 3.13.

stat.**UF_HIDDEN**
The file should not be displayed in a GUI (macOS 10.5+).

stat.**SF_SETTABLE**
All super-user changeable flags

Added in version 3.13.

stat.**SF_SUPPORTED**
All super-user supported flags

Availability: macOS

Added in version 3.13.

stat.**SF_SYNTHETIC**
All super-user read-only synthetic flags

Availability: macOS

Added in version 3.13.

stat.**SF_ARCHIVED**
The file may be archived.

stat.**SF_IMMUTABLE**
The file may not be changed.

stat.**SF_APPEND**
The file may only be appended to.

stat.**SF_RESTRICTED**
The file needs an entitlement to write to (macOS 10.13+)

Added in version 3.13.

stat.**SF_NOUNLINK**
The file may not be renamed or deleted.

stat.**SF_SNAPSHOT**
The file is a snapshot file.

stat.**SF_FIRMLINK**
The file is a firmlink (macOS 10.15+)

Added in version 3.13.

stat.**SF_DATALESS**
The file is a dataless object (macOS 10.15+)

Added in version 3.13.

See the *BSD or macOS systems man page *chflags(2)* for more information.

On Windows, the following file attribute constants are available for use when testing bits in the `st_file_attributes` member returned by *os.stat()*. See the Windows API documentation for more detail on the meaning of these constants.

stat.**FILE_ATTRIBUTE_ARCHIVE**
stat.**FILE_ATTRIBUTE_COMPRESSED**
stat.**FILE_ATTRIBUTE_DEVICE**
stat.**FILE_ATTRIBUTE_DIRECTORY**
stat.**FILE_ATTRIBUTE_ENCRYPTED**
stat.**FILE_ATTRIBUTE_HIDDEN**
stat.**FILE_ATTRIBUTE_INTEGRITY_STREAM**
stat.**FILE_ATTRIBUTE_NORMAL**
stat.**FILE_ATTRIBUTE_NOT_CONTENT_INDEXED**
stat.**FILE_ATTRIBUTE_NO_SCRUB_DATA**
stat.**FILE_ATTRIBUTE_OFFLINE**
stat.**FILE_ATTRIBUTE_READONLY**
stat.**FILE_ATTRIBUTE_REPARSE_POINT**
stat.**FILE_ATTRIBUTE_SPARSE_FILE**
stat.**FILE_ATTRIBUTE_SYSTEM**
stat.**FILE_ATTRIBUTE_TEMPORARY**
stat.**FILE_ATTRIBUTE_VIRTUAL**
Added in version 3.5.

On Windows, the following constants are available for comparing against the `st_reparse_tag` member returned by *os.lstat()*. These are well-known constants, but are not an exhaustive list.

stat.**IO_REPARSE_TAG_SYMLINK**
stat.**IO_REPARSE_TAG_MOUNT_POINT**
stat.**IO_REPARSE_TAG_APPEXECLINK**
Added in version 3.8.

11.4 `filecmp` — File and Directory Comparisons

Source code: Lib/filecmp.py

The *filecmp* module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the *difflib* module.

The *filecmp* module defines the following functions:

filecmp.**cmp**(*f1*, *f2*, *shallow=True*)
Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

If *shallow* is true and the *os.stat()* signatures (file type, size, and modification time) of both files are identical, the files are taken to be equal.

Otherwise, the files are treated as different if their sizes or contents differ.

Note that no external programs are called from this function, giving it portability and efficiency.

This function uses a cache for past comparisons and the results, with cache entries invalidated if the *os.stat()* information for the file changes. The entire cache may be cleared using *clear_cache()*.

filecmp.**cmpfiles**(*dir1*, *dir2*, *common*, *shallow=True*)

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for *filecmp.cmp()*.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare `a/c` with `b/c` and `a/d/e` with `b/d/e`. `'c'` and `'d/e'` will each be in one of the three returned lists.

filecmp.**clear_cache**()

Clear the filecmp cache. This may be useful if a file is compared so quickly after it is modified that it is within the mtime resolution of the underlying filesystem.

Added in version 3.4.

11.4.1 The `dircmp` class

class filecmp.**dircmp**(*a*, *b*, *ignore=None*, *hide=None*, ***, *shallow=True*)

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to *filecmp.DEFAULT_IGNORES*. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The *dircmp* class compares files by doing *shallow* comparisons as described for *filecmp.cmp()* by default using the *shallow* parameter.

Changed in version 3.13: Added the *shallow* parameter.

The *dircmp* class provides the following methods:

report()

Print (to *sys.stdout*) a comparison between *a* and *b*.

report_partial_closure()

Print a comparison between *a* and *b* and common immediate subdirectories.

report_full_closure()

Print a comparison between *a* and *b* and common subdirectories (recursively).

The *dircmp* class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

left

The directory *a*.

right

The directory *b*.

left_list

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

right_list

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

common

Files and subdirectories in both *a* and *b*.

left_only
: Files and subdirectories only in *a*.

right_only
: Files and subdirectories only in *b*.

common_dirs
: Subdirectories in both *a* and *b*.

common_files
: Files in both *a* and *b*.

common_funny
: Names in both *a* and *b*, such that the type differs between the directories, or names for which *os.stat()* reports an error.

same_files
: Files which are identical in both *a* and *b*, using the class's file comparison operator.

diff_files
: Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

funny_files
: Files which are in both *a* and *b*, but could not be compared.

subdirs
: A dictionary mapping names in *common_dirs* to *dircmp* instances (or MyDirCmp instances if this instance is of type MyDirCmp, a subclass of *dircmp*).

  Changed in version 3.10: Previously entries were always *dircmp* instances. Now entries are the same type as *self*, if *self* is a subclass of *dircmp*.

filecmp.**DEFAULT_IGNORES**
: Added in version 3.4.

  List of directories ignored by *dircmp* by default.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print("diff_file %s found in %s and %s" % (name, dcmp.left,
...               dcmp.right))
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

11.5 tempfile — Generate temporary files and directories

Source code: Lib/tempfile.py

This module creates temporary files and directories. It works on all supported platforms. *TemporaryFile*, *NamedTemporaryFile*, *TemporaryDirectory*, and *SpooledTemporaryFile* are high-level interfaces which provide automatic cleanup and can be used as *context managers*. *mkstemp()* and *mkdtemp()* are lower-level functions which require manual cleanup.

All the user-callable functions and constructors take additional arguments which allow direct control over the location and name of temporary files and directories. Files names used by this module include a string of random characters which allows those files to be securely created in shared temporary directories. To maintain backward compatibility, the argument order is somewhat odd; it is recommended to use keyword arguments for clarity.

The module defines the following user-callable items:

tempfile.**TemporaryFile**(*mode='w+b'*, *buffering=-1*, *encoding=None*, *newline=None*, *suffix=None*, *prefix=None*, *dir=None*, ***, *errors=None*)

Return a *file-like object* that can be used as a temporary storage area. The file is created securely, using the same rules as `mkstemp()`. It will be destroyed as soon as it is closed (including an implicit close when the object is garbage collected). Under Unix, the directory entry for the file is either not created at all or is removed immediately after the file is created. Other platforms do not support this; your code should not rely on a temporary file created using this function having or not having a visible name in the file system.

The resulting object can be used as a *context manager* (see *Examples*). On completion of the context or destruction of the file object the temporary file will be removed from the filesystem.

The *mode* parameter defaults to `'w+b'` so that the file created can be read and written without being closed. Binary mode is used so that it behaves consistently on all platforms without regard for the data that is stored. *buffering*, *encoding*, *errors* and *newline* are interpreted as for `open()`.

The *dir*, *prefix* and *suffix* parameters have the same meaning and defaults as with `mkstemp()`.

The returned object is a true file object on POSIX platforms. On other platforms, it is a file-like object whose `file` attribute is the underlying true file object.

The `os.O_TMPFILE` flag is used if it is available and works (Linux-specific, requires Linux kernel 3.11 or later).

On platforms that are neither Posix nor Cygwin, TemporaryFile is an alias for NamedTemporaryFile.

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

Changed in version 3.5: The `os.O_TMPFILE` flag is now used if available.

Changed in version 3.8: Added *errors* parameter.

tempfile.**NamedTemporaryFile**(*mode='w+b'*, *buffering=-1*, *encoding=None*, *newline=None*, *suffix=None*, *prefix=None*, *dir=None*, *delete=True*, ***, *errors=None*, *delete_on_close=True*)

This function operates exactly as `TemporaryFile()` does, except the following differences:

- This function returns a file that is guaranteed to have a visible name in the file system.
- To manage the named file, it extends the parameters of `TemporaryFile()` with *delete* and *delete_on_close* parameters that determine whether and how the named file should be automatically deleted.

The returned object is always a *file-like object* whose `file` attribute is the underlying true file object. This file-like object can be used in a `with` statement, just like a normal file. The name of the temporary file can be retrieved from the `name` attribute of the returned file-like object. On Unix, unlike with the `TemporaryFile()`, the directory entry does not get unlinked immediately after the file creation.

If *delete* is true (the default) and *delete_on_close* is true (the default), the file is deleted as soon as it is closed. If *delete* is true and *delete_on_close* is false, the file is deleted on context manager exit only, or else when the *file-like object* is finalized. Deletion is not always guaranteed in this case (see `object.__del__()`). If *delete* is false, the value of *delete_on_close* is ignored.

Therefore to use the name of the temporary file to reopen the file after closing it, either make sure not to delete the file upon closure (set the *delete* parameter to be false) or, in case the temporary file is created in a `with` statement, set the *delete_on_close* parameter to be false. The latter approach is recommended as it provides assistance in automatic cleaning of the temporary file upon the context manager exit.

Opening the temporary file again by its name while it is still open works as follows:

- On POSIX the file can always be opened again.

- On Windows, make sure that at least one of the following conditions are fulfilled:
  - *delete* is false
  - additional open shares delete access (e.g. by calling `os.open()` with the flag `O_TEMPORARY`)
  - *delete* is true but *delete_on_close* is false. Note, that in this case the additional opens that do not share delete access (e.g. created via builtin `open()`) must be closed before exiting the context manager, else the `os.unlink()` call on context manager exit will fail with a `PermissionError`.

On Windows, if *delete_on_close* is false, and the file is created in a directory for which the user lacks delete access, then the `os.unlink()` call on exit of the context manager will fail with a `PermissionError`. This cannot happen when *delete_on_close* is true because delete access is requested by the open, which fails immediately if the requested access is not granted.

On POSIX (only), a process that is terminated abruptly with SIGKILL cannot automatically delete any NamedTemporaryFiles it created.

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

Changed in version 3.8: Added *errors* parameter.

Changed in version 3.12: Added *delete_on_close* parameter.

class tempfile.**SpooledTemporaryFile**(*max_size=0*, *mode='w+b'*, *buffering=-1*, *encoding=None*, *newline=None*, *suffix=None*, *prefix=None*, *dir=None*, ***, *errors=None*)

This class operates exactly as `TemporaryFile()` does, except that data is spooled in memory until the file size exceeds *max_size*, or until the file's `fileno()` method is called, at which point the contents are written to disk and operation proceeds as with `TemporaryFile()`.

rollover()

The resulting file has one additional method, `rollover()`, which causes the file to roll over to an on-disk file regardless of its size.

The returned object is a file-like object whose `_file` attribute is either an `io.BytesIO` or `io.TextIOWrapper` object (depending on whether binary or text *mode* was specified) or a true file object, depending on whether `rollover()` has been called. This file-like object can be used in a `with` statement, just like a normal file.

Changed in version 3.3: the truncate method now accepts a *size* argument.

Changed in version 3.8: Added *errors* parameter.

Changed in version 3.11: Fully implements the `io.BufferedIOBase` and `io.TextIOBase` abstract base classes (depending on whether binary or text *mode* was specified).

class tempfile.**TemporaryDirectory**(*suffix=None*, *prefix=None*, *dir=None*, *ignore_cleanup_errors=False*, ***, *delete=True*)

This class securely creates a temporary directory using the same rules as `mkdtemp()`. The resulting object can be used as a *context manager* (see *Examples*). On completion of the context or destruction of the temporary directory object, the newly created temporary directory and all its contents are removed from the filesystem.

name

The directory name can be retrieved from the `name` attribute of the returned object. When the returned object is used as a *context manager*, the `name` will be assigned to the target of the `as` clause in the `with` statement, if there is one.

cleanup()

The directory can be explicitly cleaned up by calling the `cleanup()` method. If *ignore_cleanup_errors* is true, any unhandled exceptions during explicit or implicit cleanup (such as a `PermissionError` removing open files on Windows) will be ignored, and the remaining removable items deleted on a "best-effort" basis. Otherwise, errors will be raised in whatever context cleanup occurs (the `cleanup()` call, exiting the context manager, when the object is garbage-collected or during interpreter shutdown).

The *delete* parameter can be used to disable cleanup of the directory tree upon exiting the context. While it may seem unusual for a context manager to disable the action taken when exiting the context, it can be useful during debugging or when you need your cleanup behavior to be conditional based on other logic.

Raises an *auditing event* `tempfile.mkdtemp` with argument `fullpath`.

Added in version 3.2.

Changed in version 3.10: Added *ignore_cleanup_errors* parameter.

Changed in version 3.12: Added the *delete* parameter.

`tempfile.`**`mkstemp`**(*suffix=None*, *prefix=None*, *dir=None*, *text=False*)

Creates a temporary file in the most secure manner possible. There are no race conditions in the file's creation, assuming that the platform properly implements the `os.O_EXCL` flag for `os.open()`. The file is readable and writable only by the creating user ID. If the platform uses permission bits to indicate whether a file is executable, the file is executable by no one. The file descriptor is not inherited by child processes.

Unlike `TemporaryFile()`, the user of `mkstemp()` is responsible for deleting the temporary file when done with it.

If *suffix* is not `None`, the file name will end with that suffix, otherwise there will be no suffix. `mkstemp()` does not put a dot between the file name and the suffix; if you need one, put it at the beginning of *suffix*.

If *prefix* is not `None`, the file name will begin with that prefix; otherwise, a default prefix is used. The default is the return value of `gettempprefix()` or `gettempprefixb()`, as appropriate.

If *dir* is not `None`, the file will be created in that directory; otherwise, a default directory is used. The default directory is chosen from a platform-dependent list, but the user of the application can control the directory location by setting the *TMPDIR*, *TEMP* or *TMP* environment variables. There is thus no guarantee that the generated filename will have any nice properties, such as not requiring quoting when passed to external commands via `os.popen()`.

If any of *suffix*, *prefix*, and *dir* are not `None`, they must be the same type. If they are bytes, the returned name will be bytes instead of str. If you want to force a bytes return value with otherwise default behavior, pass `suffix=b''`.

If *text* is specified and true, the file is opened in text mode. Otherwise, (the default) the file is opened in binary mode.

`mkstemp()` returns a tuple containing an OS-level handle to an open file (as would be returned by `os.open()`) and the absolute pathname of that file, in that order.

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

Changed in version 3.5: *suffix*, *prefix*, and *dir* may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only str was allowed. *suffix* and *prefix* now accept and default to `None` to cause an appropriate default value to be used.

Changed in version 3.6: The *dir* parameter now accepts a *path-like object*.

`tempfile.`**`mkdtemp`**(*suffix=None*, *prefix=None*, *dir=None*)

Creates a temporary directory in the most secure manner possible. There are no race conditions in the directory's creation. The directory is readable, writable, and searchable only by the creating user ID.

The user of `mkdtemp()` is responsible for deleting the temporary directory and its contents when done with it.

The *prefix*, *suffix*, and *dir* arguments are the same as for `mkstemp()`.

`mkdtemp()` returns the absolute pathname of the new directory.

Raises an *auditing event* `tempfile.mkdtemp` with argument `fullpath`.

Changed in version 3.5: *suffix*, *prefix*, and *dir* may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only str was allowed. *suffix* and *prefix* now accept and default to `None` to cause an appropriate default value to be used.

Changed in version 3.6: The *dir* parameter now accepts a *path-like object*.

Changed in version 3.12: *mkdtemp()* now always returns an absolute path, even if *dir* is relative.

tempfile.**gettempdir**()

Return the name of the directory used for temporary files. This defines the default value for the *dir* argument to all functions in this module.

Python searches a standard list of directories to find one which the calling user can create files in. The list is:

1. The directory named by the TMPDIR environment variable.
2. The directory named by the TEMP environment variable.
3. The directory named by the TMP environment variable.
4. A platform-specific location:
   - On Windows, the directories C:\TEMP, C:\TMP, \TEMP, and \TMP, in that order.
   - On all other platforms, the directories /tmp, /var/tmp, and /usr/tmp, in that order.
5. As a last resort, the current working directory.

The result of this search is cached, see the description of *tempdir* below.

Changed in version 3.10: Always returns a str. Previously it would return any *tempdir* value regardless of type so long as it was not None.

tempfile.**gettempdirb**()

Same as *gettempdir()* but the return value is in bytes.

Added in version 3.5.

tempfile.**gettempprefix**()

Return the filename prefix used to create temporary files. This does not contain the directory component.

tempfile.**gettempprefixb**()

Same as *gettempprefix()* but the return value is in bytes.

Added in version 3.5.

The module uses a global variable to store the name of the directory used for temporary files returned by *gettempdir()*. It can be set directly to override the selection process, but this is discouraged. All functions in this module take a *dir* argument which can be used to specify the directory. This is the recommended approach that does not surprise other unsuspecting code by changing global API behavior.

tempfile.**tempdir**

When set to a value other than None, this variable defines the default value for the *dir* argument to the functions defined in this module, including its type, bytes or str. It cannot be a *path-like object*.

If tempdir is None (the default) at any call to any of the above functions except *gettempprefix()* it is initialized following the algorithm described in *gettempdir()*.

Note

Beware that if you set tempdir to a bytes value, there is a nasty side effect: The global default return type of *mkstemp()* and *mkdtemp()* changes to bytes when no explicit prefix, suffix, or dir arguments of type str are supplied. Please do not write code expecting or depending on this. This awkward behavior is maintained for compatibility with the historical implementation.

11.5.1 Examples

Here are some examples of typical usage of the *tempfile* module:

```
>>> import tempfile

# create a temporary file and write some data to it
>>> fp = tempfile.TemporaryFile()
>>> fp.write(b'Hello world!')
# read data from file
>>> fp.seek(0)
>>> fp.read()
b'Hello world!'
# close the file, it will be removed
>>> fp.close()

# create a temporary file using a context manager
>>> with tempfile.TemporaryFile() as fp:
...     fp.write(b'Hello world!')
...     fp.seek(0)
...     fp.read()
b'Hello world!'
>>>
# file is now closed and removed

# create a temporary file using a context manager
# close the file, use the name to open the file again
>>> with tempfile.NamedTemporaryFile(delete_on_close=False) as fp:
...     fp.write(b'Hello world!')
...     fp.close()
... # the file is closed, but not removed
... # open the file again by using its name
...     with open(fp.name, mode='rb') as f:
...         f.read()
b'Hello world!'
>>>
# file is now removed

# create a temporary directory using the context manager
>>> with tempfile.TemporaryDirectory() as tmpdirname:
...     print('created temporary directory', tmpdirname)
>>>
# directory and contents have been removed
```

11.5.2 Deprecated functions and variables

A historical way to create temporary files was to first generate a file name with the *mktemp()* function and then create a file using this name. Unfortunately this is not secure, because a different process may create a file with this name in the time between the call to *mktemp()* and the subsequent attempt to create the file by the first process. The solution is to combine the two steps and create the file immediately. This approach is used by *mkstemp()* and the other functions described above.

`tempfile.`**`mktemp`**(*suffix=''*, *prefix='tmp'*, *dir=None*)

Deprecated since version 2.3: Use *mkstemp()* instead.

Return an absolute pathname of a file that did not exist at the time the call is made. The *prefix*, *suffix*, and *dir* arguments are similar to those of *mkstemp()*, except that bytes file names, `suffix=None` and `prefix=None` are not supported.

Warning

Use of this function may introduce a security hole in your program. By the time you get around to doing anything with the file name it returns, someone else may have beaten you to the punch. *mktemp()* usage can be replaced easily with *NamedTemporaryFile()*, passing it the `delete=False` parameter:

```
>>> f = NamedTemporaryFile(delete=False)
>>> f.name
'/tmp/tmptjujjt'
>>> f.write(b"Hello World!\n")
13
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False
```

11.6 `glob` — Unix style pathname pattern expansion

Source code: Lib/glob.py

The *glob* module finds all the pathnames matching a specified pattern according to the rules used by the Unix shell, although results are returned in arbitrary order. No tilde expansion is done, but `*`, `?`, and character ranges expressed with `[]` will be correctly matched. This is done by using the *os.scandir()* and *fnmatch.fnmatch()* functions in concert, and not by actually invoking a subshell.

Note that files beginning with a dot (`.`) can only be matched by patterns that also start with a dot, unlike *fnmatch.fnmatch()* or *pathlib.Path.glob()*. (For tilde and shell variable expansion, use *os.path.expanduser()* and *os.path.expandvars()*.)

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

The *glob* module defines the following functions:

`glob.`**`glob`**(*pathname*, ***, *root_dir=None*, *dir_fd=None*, *recursive=False*, *include_hidden=False*)

Return a possibly empty list of path names that match *pathname*, which must be a string containing a path specification. *pathname* can be either absolute (like `/usr/src/Python-1.5/Makefile`) or relative (like `../../Tools/*/*.gif`), and can contain shell-style wildcards. Broken symlinks are included in the results (as in the shell). Whether or not the results are sorted depends on the file system. If a file that satisfies conditions is removed or added during the call of this function, whether a path name for that file will be included is unspecified.

If *root_dir* is not `None`, it should be a *path-like object* specifying the root directory for searching. It has the same effect on *glob()* as changing the current directory before calling it. If *pathname* is relative, the result will contain paths relative to *root_dir*.

This function can support *paths relative to directory descriptors* with the *dir_fd* parameter.

If *recursive* is true, the pattern "`**`" will match any files and zero or more directories, subdirectories and symbolic links to directories. If the pattern is followed by an *os.sep* or *os.altsep* then files will not match.

If *include_hidden* is true, "`**`" pattern will match hidden directories.

Raises an *auditing event* `glob.glob` with arguments `pathname`, `recursive`.

Raises an *auditing event* `glob.glob/2` with arguments `pathname`, `recursive`, `root_dir`, `dir_fd`.

Note

Using the "`**`" pattern in large directory trees may consume an inordinate amount of time.

> **Note**
>
> This function may return duplicate path names if *pathname* contains multiple "`**`" patterns and *recursive* is true.

Changed in version 3.5: Support for recursive globs using "`**`".

Changed in version 3.10: Added the *root_dir* and *dir_fd* parameters.

Changed in version 3.11: Added the *include_hidden* parameter.

`glob.`**`iglob`**(*pathname*, *, *root_dir=None*, *dir_fd=None*, *recursive=False*, *include_hidden=False*)

Return an *iterator* which yields the same values as `glob()` without actually storing them all simultaneously.

Raises an *auditing event* `glob.glob` with arguments `pathname`, `recursive`.

Raises an *auditing event* `glob.glob/2` with arguments `pathname`, `recursive`, `root_dir`, `dir_fd`.

> **Note**
>
> This function may return duplicate path names if *pathname* contains multiple "`**`" patterns and *recursive* is true.

Changed in version 3.5: Support for recursive globs using "`**`".

Changed in version 3.10: Added the *root_dir* and *dir_fd* parameters.

Changed in version 3.11: Added the *include_hidden* parameter.

`glob.`**`escape`**(*pathname*)

Escape all special characters (`'?'`, `'*'` and `'['`). This is useful if you want to match an arbitrary literal string that may have special characters in it. Special characters in drive/UNC sharepoints are not escaped, e.g. on Windows `escape('//?/c:/Quo vadis?.txt')` returns `'//?/c:/Quo vadis[?].txt'`.

Added in version 3.4.

`glob.`**`translate`**(*pathname*, *, *recursive=False*, *include_hidden=False*, *seps=None*)

Convert the given path specification to a regular expression for use with `re.match()`. The path specification can contain shell-style wildcards.

For example:

```
>>> import glob, re
>>>
>>> regex = glob.translate('**/*.txt', recursive=True, include_hidden=True)
>>> regex
'(?s:(?:.+/)?[^/]*\\.txt)\\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foo/bar/baz.txt')
<re.Match object; span=(0, 15), match='foo/bar/baz.txt'>
```

Path separators and segments are meaningful to this function, unlike `fnmatch.translate()`. By default wildcards do not match path separators, and `*` pattern segments match precisely one path segment.

If *recursive* is true, the pattern segment "`**`" will match any number of path segments.

If *include_hidden* is true, wildcards can match path segments that start with a dot (`.`).

A sequence of path separators may be supplied to the *seps* argument. If not given, `os.sep` and `altsep` (if available) are used.

> **See also**
>
> *pathlib.PurePath.full_match()* and *pathlib.Path.glob()* methods, which call this function to implement pattern matching and globbing.

Added in version 3.13.

11.6.1 Examples

Consider a directory containing the following files: `1.gif`, `2.txt`, `card.gif` and a subdirectory `sub` which contains only the file `3.txt`. *glob()* will produce the following results. Notice how any leading components of the path are preserved.

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
['1.gif']
>>> glob.glob('**/*.txt', recursive=True)
['2.txt', 'sub/3.txt']
>>> glob.glob('./**/', recursive=True)
['./', './sub/']
```

If the directory contains files starting with `.` they won't be matched by default. For example, consider a directory containing `card.gif` and `.card.gif`:

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.c*')
['.card.gif']
```

> **See also**
>
> The *pathlib* module offers high-level path objects.

11.7 `fnmatch` — Unix filename pattern matching

Source code: Lib/fnmatch.py

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the *re* module). The special characters used in shell-style wildcards are:

Pattern	Meaning
`*`	matches everything
`?`	matches any single character
`[seq]`	matches any character in *seq*
`[!seq]`	matches any character not in *seq*

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module *glob* for pathname expansion (*glob* uses *filter()* to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

Unless stated otherwise, "filename string" and "pattern string" either refer to *str* or `ISO-8859-1` encoded *bytes* objects. Note that the functions documented below do not allow to mix a `bytes` pattern with a `str` filename, and vice-versa.

Finally, note that *functools.lru_cache()* with a *maxsize* of 32768 is used to cache the (typed) compiled regex patterns in the following functions: *fnmatch()*, *fnmatchcase()*, *filter()*.

`fnmatch.`**`fnmatch`**(*name*, *pat*)

Test whether the filename string *name* matches the pattern string *pat*, returning `True` or `False`. Both parameters are case-normalized using *os.path.normcase()*. *fnmatchcase()* can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print(file)
```

`fnmatch.`**`fnmatchcase`**(*name*, *pat*)

Test whether the filename string *name* matches the pattern string *pat*, returning `True` or `False`; the comparison is case-sensitive and does not apply *os.path.normcase()*.

`fnmatch.`**`filter`**(*names*, *pat*)

Construct a list from those elements of the *iterable* of filename strings *names* that match the pattern string *pat*. It is the same as `[n for n in names if fnmatch(n, pat)]`, but implemented more efficiently.

`fnmatch.`**`translate`**(*pat*)

Return the shell-style pattern *pat* converted to a regular expression for using with *re.match()*. The pattern is expected to be a *str*.

Example:

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'(?s:.*\\.txt)\\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<re.Match object; span=(0, 10), match='foobar.txt'>
```

Module *glob*
Unix shell-style path expansion.

11.8 linecache — Random access to text lines

Source code: Lib/linecache.py

The *linecache* module allows one to get any line from a Python source file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the *traceback* module to retrieve source lines for inclusion in the formatted traceback.

The *tokenize.open()* function is used to open files. This function uses *tokenize.detect_encoding()* to get the encoding of the file; in the absence of an encoding token, the file encoding defaults to UTF-8.

The *linecache* module defines the following functions:

linecache.**getline**(*filename*, *lineno*, *module_globals=None*)

Get line *lineno* from file named *filename*. This function will never raise an exception — it will return `''` on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function first checks for a **PEP 302** `__loader__` in *module_globals*. If there is such a loader and it defines a `get_source` method, then that determines the source lines (if `get_source()` returns `None`, then `''` is returned). Finally, if *filename* is a relative filename, it is looked up relative to the entries in the module search path, `sys.path`.

linecache.**clearcache**()

Clear the cache. Use this function if you no longer need lines from files previously read using *getline()*.

linecache.**checkcache**(*filename=None*)

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If *filename* is omitted, it will check all the entries in the cache.

linecache.**lazycache**(*filename*, *module_globals*)

Capture enough detail about a non-file-based module to permit getting its lines later via *getline()* even if *module_globals* is `None` in the later call. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely.

Added in version 3.5.

Example:

```
>>> import linecache
>>> linecache.getline(linecache.__file__, 8)
'import sys\n'
```

11.9 shutil — High-level file operations

Source code: Lib/shutil.py

The *shutil* module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the *os* module.

Warning

Even the higher-level file copying functions (`shutil.copy()`, `shutil.copy2()`) cannot copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

11.9.1 Directory and files operations

`shutil.`**`copyfileobj`**(*fsrc*, *fdst*[, *length*])

Copy the contents of the *file-like object* *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.`**`copyfile`**(*src*, *dst*, ***, *follow_symlinks=True*)

Copy the contents (no metadata) of the file named *src* to a file named *dst* and return *dst* in the most efficient way possible. *src* and *dst* are *path-like objects* or path names given as strings.

dst must be the complete target file name; look at `copy()` for a copy that accepts a target directory path. If *src* and *dst* specify the same file, `SameFileError` is raised.

The destination location must be writable; otherwise, an `OSError` exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function.

If *follow_symlinks* is false and *src* is a symbolic link, a new symbolic link will be created instead of copying the file *src* points to.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Changed in version 3.3: `IOError` used to be raised instead of `OSError`. Added *follow_symlinks* argument. Now returns *dst*.

Changed in version 3.4: Raise `SameFileError` instead of `Error`. Since the former is a subclass of the latter, this change is backward compatible.

Changed in version 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

exception `shutil.`**`SameFileError`**

This exception is raised if source and destination in `copyfile()` are the same file.

Added in version 3.4.

`shutil.`**`copymode`**(*src*, *dst*, ***, *follow_symlinks=True*)

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are *path-like objects* or path names given as strings. If *follow_symlinks* is false, and both *src* and *dst* are symbolic links, `copymode()` will attempt to modify the mode of *dst* itself (rather than the file it points to). This functionality is not available on every platform; please see `copystat()` for more information. If `copymode()` cannot modify symbolic links on the local platform, and it is asked to do so, it will do nothing and return.

Raises an *auditing event* `shutil.copymode` with arguments `src`, `dst`.

Changed in version 3.3: Added *follow_symlinks* argument.

`shutil.`**`copystat`**(*src*, *dst*, ***, *follow_symlinks=True*)

Copy the permission bits, last access time, last modification time, and flags from *src* to *dst*. On Linux, `copystat()` also copies the "extended attributes" where possible. The file contents, owner, and group are unaffected. *src* and *dst* are *path-like objects* or path names given as strings.

If *follow_symlinks* is false, and *src* and *dst* both refer to symbolic links, *copystat()* will operate on the symbolic links themselves rather than the files the symbolic links refer to—reading the information from the *src* symbolic link, and writing the information to the *dst* symbolic link.

> **Note**
>
> Not all platforms provide the ability to examine and modify symbolic links. Python itself can tell you what functionality is locally available.
>
> - If `os.chmod in os.supports_follow_symlinks` is `True`, *copystat()* can modify the permission bits of a symbolic link.
> - If `os.utime in os.supports_follow_symlinks` is `True`, *copystat()* can modify the last access and modification times of a symbolic link.
> - If `os.chflags in os.supports_follow_symlinks` is `True`, *copystat()* can modify the flags of a symbolic link. (`os.chflags` is not available on all platforms.)
>
> On platforms where some or all of this functionality is unavailable, when asked to modify a symbolic link, *copystat()* will copy everything it can. *copystat()* never returns failure.
>
> Please see *os.supports_follow_symlinks* for more information.

Raises an *auditing event* `shutil.copystat` with arguments `src`, `dst`.

Changed in version 3.3: Added *follow_symlinks* argument and support for Linux extended attributes.

`shutil.`**`copy`**(*src*, *dst*, ***, *follow_symlinks=True*)

Copies the file *src* to the file or directory *dst*. *src* and *dst* should be *path-like objects* or strings. If *dst* specifies a directory, the file will be copied into *dst* using the base filename from *src*. If *dst* specifies a file that already exists, it will be replaced. Returns the path to the newly created file.

If *follow_symlinks* is false, and *src* is a symbolic link, *dst* will be created as a symbolic link. If *follow_symlinks* is true and *src* is a symbolic link, *dst* will be a copy of the file *src* refers to.

copy() copies the file data and the file's permission mode (see *os.chmod()*). Other metadata, like the file's creation and modification times, is not preserved. To preserve all file metadata from the original, use *copy2()* instead.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Raises an *auditing event* `shutil.copymode` with arguments `src`, `dst`.

Changed in version 3.3: Added *follow_symlinks* argument. Now returns path to the newly created file.

Changed in version 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

`shutil.`**`copy2`**(*src*, *dst*, ***, *follow_symlinks=True*)

Identical to *copy()* except that *copy2()* also attempts to preserve file metadata.

When *follow_symlinks* is false, and *src* is a symbolic link, *copy2()* attempts to copy all metadata from the *src* symbolic link to the newly created *dst* symbolic link. However, this functionality is not available on all platforms. On platforms where some or all of this functionality is unavailable, *copy2()* will preserve all the metadata it can; *copy2()* never raises an exception because it cannot preserve file metadata.

copy2() uses *copystat()* to copy the file metadata. Please see *copystat()* for more information about platform support for modifying symbolic link metadata.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Raises an *auditing event* `shutil.copystat` with arguments `src`, `dst`.

Changed in version 3.3: Added *follow_symlinks* argument, try to copy extended file system attributes too (currently Linux only). Now returns path to the newly created file.

Changed in version 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

shutil.**ignore_patterns**(**patterns*)

This factory function creates a function that can be used as a callable for `copytree()`'s *ignore* argument, ignoring files and directories that match one of the glob-style *patterns* provided. See the example below.

shutil.**copytree**(*src*, *dst*, *symlinks=False*, *ignore=None*, *copy_function=copy2*, *ignore_dangling_symlinks=False*, *dirs_exist_ok=False*)

Recursively copy an entire directory tree rooted at *src* to a directory named *dst* and return the destination directory. All intermediate directories needed to contain *dst* will also be created by default.

Permissions and times of directories are copied with `copystat()`, individual files are copied using `copy2()`.

If *symlinks* is true, symbolic links in the source tree are represented as symbolic links in the new tree and the metadata of the original links will be copied as far as the platform allows; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

When *symlinks* is false, if the file pointed to by the symlink doesn't exist, an exception will be added in the list of errors raised in an `Error` exception at the end of the copy process. You can set the optional *ignore_dangling_symlinks* flag to true if you want to silence this exception. Notice that this option has no effect on platforms that don't support `os.symlink()`.

If *ignore* is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the *ignore* callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an `Error` is raised with a list of reasons.

If *copy_function* is given, it must be a callable that will be used to copy each file. It will be called with the source path and the destination path as arguments. By default, `copy2()` is used, but any function that supports the same signature (like `copy()`) can be used.

If *dirs_exist_ok* is false (the default) and *dst* already exists, a `FileExistsError` is raised. If *dirs_exist_ok* is true, the copying operation will continue if it encounters existing directories, and files within the *dst* tree will be overwritten by corresponding files from the *src* tree.

Raises an *auditing event* `shutil.copytree` with arguments `src`, `dst`.

Changed in version 3.2: Added the *copy_function* argument to be able to provide a custom copy function. Added the *ignore_dangling_symlinks* argument to silence dangling symlinks errors when *symlinks* is false.

Changed in version 3.3: Copy metadata when *symlinks* is false. Now returns *dst*.

Changed in version 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

Changed in version 3.8: Added the *dirs_exist_ok* parameter.

shutil.**rmtree**(*path*, *ignore_errors=False*, *onerror=None*, ***, *onexc=None*, *dir_fd=None*)

Delete an entire directory tree; *path* must point to a directory (but not a symbolic link to a directory). If *ignore_errors* is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by *onexc* or *onerror* or, if both are omitted, exceptions are propagated to the caller.

This function can support *paths relative to directory descriptors*.

Note

On platforms that support the necessary fd-based functions a symlink attack resistant version of `rmtree()` is used by default. On other platforms, the `rmtree()` implementation is susceptible to a symlink attack:

given proper timing and circumstances, attackers can manipulate symlinks on the filesystem to delete files they wouldn't be able to access otherwise. Applications can use the *rmtree.avoids_symlink_attacks* function attribute to determine which case applies.

If *onexc* is provided, it must be a callable that accepts three parameters: *function*, *path*, and *excinfo*.

The first parameter, *function*, is the function which raised the exception; it depends on the platform and implementation. The second parameter, *path*, will be the path name passed to *function*. The third parameter, *excinfo*, is the exception that was raised. Exceptions raised by *onexc* will not be caught.

The deprecated *onerror* is similar to *onexc*, except that the third parameter it receives is the tuple returned from *sys.exc_info()*.

Raises an *auditing event* `shutil.rmtree` with arguments `path`, `dir_fd`.

Changed in version 3.3: Added a symlink attack resistant version that is used automatically if platform supports fd-based functions.

Changed in version 3.8: On Windows, will no longer delete the contents of a directory junction before removing the junction.

Changed in version 3.11: Added the *dir_fd* parameter.

Changed in version 3.12: Added the *onexc* parameter, deprecated *onerror*.

Changed in version 3.13: `rmtree()` now ignores *FileNotFoundError* exceptions for all but the top-level path. Exceptions other than *OSError* and subclasses of `OSError` are now always propagated to the caller.

`rmtree.`**`avoids_symlink_attacks`**

Indicates whether the current platform and implementation provides a symlink attack resistant version of *rmtree()*. Currently this is only true for platforms supporting fd-based directory access functions.

Added in version 3.3.

`shutil.`**`move`**(*src*, *dst*, *copy_function=copy2*)

Recursively move a file or directory (*src*) to another location and return the destination.

If *dst* is an existing directory or a symlink to a directory, then *src* is moved inside that directory. The destination path in that directory must not already exist.

If *dst* already exists but is not a directory, it may be overwritten depending on *os.rename()* semantics.

If the destination is on the current filesystem, then *os.rename()* is used. Otherwise, *src* is copied to the destination using *copy_function* and then removed. In case of symlinks, a new symlink pointing to the target of *src* will be created as the destination and *src* will be removed.

If *copy_function* is given, it must be a callable that takes two arguments, *src* and the destination, and will be used to copy *src* to the destination if *os.rename()* cannot be used. If the source is a directory, *copytree()* is called, passing it the *copy_function*. The default *copy_function* is *copy2()*. Using *copy()* as the *copy_function* allows the move to succeed when it is not possible to also copy the metadata, at the expense of not copying any of the metadata.

Raises an *auditing event* `shutil.move` with arguments `src`, `dst`.

Changed in version 3.3: Added explicit symlink handling for foreign filesystems, thus adapting it to the behavior of GNU's **mv**. Now returns *dst*.

Changed in version 3.5: Added the *copy_function* keyword argument.

Changed in version 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

Changed in version 3.9: Accepts a *path-like object* for both *src* and *dst*.

shutil.**disk_usage**(*path*)

Return disk usage statistics about the given path as a *named tuple* with the attributes *total*, *used* and *free*, which are the amount of total, used and free space, in bytes. *path* may be a file or a directory.

> **Note**
>
> On Unix filesystems, *path* must point to a path within a **mounted** filesystem partition. On those platforms, CPython doesn't attempt to retrieve disk usage information from non-mounted filesystems.

Added in version 3.3.

Changed in version 3.8: On Windows, *path* can now be a file or directory.

Availability: Unix, Windows.

shutil.**chown**(*path*, *user=None*, *group=None*, *, *dir_fd=None*, *follow_symlinks=True*)

Change owner *user* and/or *group* of the given *path*.

user can be a system user name or a uid; the same applies to *group*. At least one argument is required.

See also `os.chown()`, the underlying function.

Raises an *auditing event* `shutil.chown` with arguments `path`, `user`, `group`.

Availability: Unix.

Added in version 3.3.

Changed in version 3.13: Added *dir_fd* and *follow_symlinks* parameters.

shutil.**which**(*cmd*, *mode=os.F_OK | os.X_OK*, *path=None*)

Return the path to an executable which would be run if the given *cmd* was called. If no *cmd* would be called, return `None`.

mode is a permission mask passed to `os.access()`, by default determining if the file exists and is executable.

path is a "`PATH` string" specifying the directories to look in, delimited by `os.pathsep`. When no *path* is specified, the `PATH` environment variable is read from `os.environ`, falling back to `os.defpath` if it is not set.

If *cmd* contains a directory component, `which()` only checks the specified path directly and does not search the directories listed in *path* or in the system's `PATH` environment variable.

On Windows, the current directory is prepended to the *path* if *mode* does not include `os.X_OK`. When the *mode* does include `os.X_OK`, the Windows API `NeedCurrentDirectoryForExePathW` will be consulted to determine if the current directory should be prepended to *path*. To avoid consulting the current working directory for executables: set the environment variable `NoDefaultCurrentDirectoryInExePath`.

Also on Windows, the `PATHEXT` environment variable is used to resolve commands that may not already include an extension. For example, if you call `shutil.which("python")`, `which()` will search `PATHEXT` to know that it should look for `python.exe` within the *path* directories. For example, on Windows:

```
>>> shutil.which("python")
'C:\\Python33\\python.EXE'
```

This is also applied when *cmd* is a path that contains a directory component:

```
>>> shutil.which("C:\\Python33\\python")
'C:\\Python33\\python.EXE'
```

Added in version 3.3.

Changed in version 3.8: The `bytes` type is now accepted. If *cmd* type is `bytes`, the result type is also `bytes`.

Changed in version 3.12: On Windows, the current directory is no longer prepended to the search path if *mode* includes `os.X_OK` and WinAPI `NeedCurrentDirectoryForExePathW(cmd)` is false, else the current directory is prepended even if it is already in the search path; `PATHEXT` is used now even when *cmd* includes a directory component or ends with an extension that is in `PATHEXT`; and filenames that have no extension can now be found.

exception shutil.**Error**

This exception collects exceptions that are raised during a multi-file operation. For *copytree()*, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

Platform-dependent efficient copy operations

Starting from Python 3.8, all functions involving a file copy (*copyfile()*, *copy()*, *copy2()*, *copytree()*, and *move()*) may use platform-specific "fast-copy" syscalls in order to copy the file more efficiently (see bpo-33671). "fast-copy" means that the copying operation occurs within the kernel, avoiding the use of userspace buffers in Python as in "`outfd.write(infd.read())`".

On macOS fcopyfile is used to copy the file content (not metadata).

On Linux *os.sendfile()* is used.

On Windows *shutil.copyfile()* uses a bigger default buffer size (1 MiB instead of 64 KiB) and a *memoryview()*-based variant of *shutil.copyfileobj()* is used.

If the fast-copy operation fails and no data was written in the destination file then shutil will silently fallback on using less efficient *copyfileobj()* function internally.

Changed in version 3.8.

copytree example

An example that uses the *ignore_patterns()* helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the *ignore* argument to add a logging call:

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s', path)
    return []   # nothing will be ignored

copytree(source, destination, ignore=_logpath)
```

rmtree example

This example shows how to remove a directory tree on Windows where some of the files have their read-only bit set. It uses the onexc callback to clear the readonly bit and reattempt the remove. Any subsequent failure will propagate.

```
import os, stat
import shutil

def remove_readonly(func, path, _):
    "Clear the readonly bit and reattempt the removal"
    os.chmod(path, stat.S_IWRITE)
```

(continues on next page)

(continued from previous page)

```
    func(path)

shutil.rmtree(directory, onexc=remove_readonly)
```

11.9.2 Archiving operations

Added in version 3.2.

Changed in version 3.5: Added support for the *xztar* format.

High-level utilities to create and read compressed and archived files are also provided. They rely on the `zipfile` and `tarfile` modules.

`shutil.make_archive`(*base_name*, *format*[, *root_dir*[, *base_dir*[, *verbose*[, *dry_run*[, *owner*[, *group*[, *logger*]]]]]]])

Create an archive file (such as zip or tar) and return its name.

base_name is the name of the file to create, including the path, minus any format-specific extension.

format is the archive format: one of "zip" (if the `zlib` module is available), "tar", "gztar" (if the `zlib` module is available), "bztar" (if the `bz2` module is available), or "xztar" (if the `lzma` module is available).

root_dir is a directory that will be the root directory of the archive, all paths in the archive will be relative to it; for example, we typically chdir into *root_dir* before creating the archive.

base_dir is the directory where we start archiving from; i.e. *base_dir* will be the common prefix of all files and directories in the archive. *base_dir* must be given relative to *root_dir*. See *Archiving example with base_dir* for how to use *base_dir* and *root_dir* together.

root_dir and *base_dir* both default to the current directory.

If *dry_run* is true, no archive is created, but the operations that would be executed are logged to *logger*.

owner and *group* are used when creating a tar archive. By default, uses the current owner and group.

logger must be an object compatible with **PEP 282**, usually an instance of `logging.Logger`.

The *verbose* argument is unused and deprecated.

Raises an *auditing event* `shutil.make_archive` with arguments `base_name`, `format`, `root_dir`, `base_dir`.

> **Note**
>
> This function is not thread-safe when custom archivers registered with `register_archive_format()` do not support the *root_dir* argument. In this case it temporarily changes the current working directory of the process to *root_dir* to perform archiving.

Changed in version 3.8: The modern pax (POSIX.1-2001) format is now used instead of the legacy GNU format for archives created with `format="tar"`.

Changed in version 3.10.6: This function is now made thread-safe during creation of standard `.zip` and tar archives.

`shutil.get_archive_formats`()

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple `(name, description)`.

By default `shutil` provides these formats:

- *zip*: ZIP file (if the `zlib` module is available).
- *tar*: Uncompressed tar file. Uses POSIX.1-2001 pax format for new archives.

- *gztar*: gzip'ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).
- *xztar*: xz'ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own archiver for any existing formats, by using *register_archive_format()*.

shutil.**register_archive_format**(*name*, *function*[, *extra_args*[, *description*]])

Register an archiver for the format *name*.

function is the callable that will be used to unpack archives. The callable will receive the *base_name* of the file to create, followed by the *base_dir* (which defaults to *os.curdir*) to start archiving from. Further arguments are passed as keyword arguments: *owner*, *group*, *dry_run* and *logger* (as passed in *make_archive()*).

If *function* has the custom attribute `function.supports_root_dir` set to `True`, the *root_dir* argument is passed as a keyword argument. Otherwise the current working directory of the process is temporarily changed to *root_dir* before calling *function*. In this case *make_archive()* is not thread-safe.

If given, *extra_args* is a sequence of `(name, value)` pairs that will be used as extra keywords arguments when the archiver callable is used.

description is used by *get_archive_formats()* which returns the list of archivers. Defaults to an empty string.

Changed in version 3.12: Added support for functions supporting the *root_dir* argument.

shutil.**unregister_archive_format**(*name*)

Remove the archive format *name* from the list of supported formats.

shutil.**unpack_archive**(*filename*[, *extract_dir*[, *format*[, *filter*]]])

Unpack an archive. *filename* is the full path of the archive.

extract_dir is the name of the target directory where the archive is unpacked. If not provided, the current working directory is used.

format is the archive format: one of "zip", "tar", "gztar", "bztar", or "xztar". Or any other format registered with *register_unpack_format()*. If not provided, *unpack_archive()* will use the archive file name extension and see if an unpacker was registered for that extension. In case none is found, a *ValueError* is raised.

The keyword-only *filter* argument is passed to the underlying unpacking function. For zip files, *filter* is not accepted. For tar files, it is recommended to set it to `'data'`, unless using features specific to tar and UNIX-like filesystems. (See *Extraction filters* for details.) The `'data'` filter will become the default for tar files in Python 3.14.

Raises an *auditing event* `shutil.unpack_archive` with arguments `filename`, `extract_dir`, `format`.

> **Warning**
>
> Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of the path specified in the *extract_dir* argument, e.g. members that have absolute filenames starting with "/" or filenames with two dots "..".

Changed in version 3.7: Accepts a *path-like object* for *filename* and *extract_dir*.

Changed in version 3.12: Added the *filter* argument.

shutil.**register_unpack_format**(*name*, *extensions*, *function*[, *extra_args*[, *description*]])

Registers an unpack format. *name* is the name of the format and *extensions* is a list of extensions corresponding to the format, like `.zip` for Zip files.

function is the callable that will be used to unpack archives. The callable will receive:

- the path of the archive, as a positional argument;

- the directory the archive must be extracted to, as a positional argument;
- possibly a *filter* keyword argument, if it was given to *unpack_archive()*;
- additional keyword arguments, specified by *extra_args* as a sequence of `(name, value)` tuples.

description can be provided to describe the format, and will be returned by the *get_unpack_formats()* function.

`shutil.`**`unregister_unpack_format`**`(`*name*`)`

Unregister an unpack format. *name* is the name of the format.

`shutil.`**`get_unpack_formats`**`()`

Return a list of all registered formats for unpacking. Each element of the returned sequence is a tuple `(name, extensions, description)`.

By default *shutil* provides these formats:

- *zip*: ZIP file (unpacking compressed files works only if the corresponding module is available).
- *tar*: uncompressed tar file.
- *gztar*: gzip'ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).
- *xztar*: xz'ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own unpacker for any existing formats, by using *register_unpack_format()*.

Archiving example

In this example, we create a gzip'ed tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx------ tarek/staff       0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff     609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff      65 2008-06-09 13:26:54 ./config
-rwx------ tarek/staff     668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff     609 2008-06-09 13:26:54 ./id_dsa.pub
-rw------- tarek/staff    1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff     397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff   37192 2010-02-06 18:23:10 ./known_hosts
```

Archiving example with *base_dir*

In this example, similar to the *one above*, we show how to use *make_archive()*, but this time with the usage of *base_dir*. We now have the following directory structure:

```
$ tree tmp
tmp
└── root
    └── structure
```

(continues on next page)

(continued from previous page)

```
        ├── content
        │   └── please_add.txt
        └── do_not_add.txt
```

In the final archive, `please_add.txt` should be included, but `do_not_add.txt` should not. Therefore we use the following:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> make_archive(
...     archive_name,
...     'tar',
...     root_dir='tmp/root',
...     base_dir='structure/content',
... )
'/Users/tarek/my_archive.tar'
```

Listing the files in the resulting archive gives us:

```
$ python -m tarfile -l /Users/tarek/myarchive.tar
structure/content/
structure/content/please_add.txt
```

11.9.3 Querying the size of the output terminal

`shutil.`**`get_terminal_size`**(*fallback=(columns, lines)*)

Get the size of the terminal window.

For each of the two dimensions, the environment variable, `COLUMNS` and `LINES` respectively, is checked. If the variable is defined and the value is a positive integer, it is used.

When `COLUMNS` or `LINES` is not defined, which is the common case, the terminal connected to *sys.__stdout__* is queried by invoking *os.get_terminal_size()*.

If the terminal size cannot be successfully queried, either because the system doesn't support querying, or because we are not connected to a terminal, the value given in `fallback` parameter is used. `fallback` defaults to `(80, 24)` which is the default size used by many terminal emulators.

The value returned is a named tuple of type *os.terminal_size*.

See also: The Single UNIX Specification, Version 2, Other Environment Variables.

Added in version 3.3.

Changed in version 3.11: The `fallback` values are also used if *os.get_terminal_size()* returns zeroes.

See also

Module *os*
Operating system interfaces, including functions to work with files at a lower level than Python *file objects*.

Module *io*
Python's built-in I/O library, including both abstract classes and some concrete classes such as file I/O.

Built-in function *open()*
The standard way to open files for reading and writing with Python.

CHAPTER

TWELVE

DATA PERSISTENCE

The modules described in this chapter support storing Python data in a persistent form on disk. The *pickle* and *marshal* modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings.

The list of modules described in this chapter is:

12.1 pickle — Python object serialization

Source code: Lib/pickle.py

The *pickle* module implements binary protocols for serializing and de-serializing a Python object structure. *"Pickling"* is the process whereby a Python object hierarchy is converted into a byte stream, and *"unpickling"* is the inverse operation, whereby a byte stream (from a *binary file* or *bytes-like object*) is converted back into an object hierarchy. Pickling (and unpickling) is alternatively known as "serialization", "marshalling,"[1] or "flattening"; however, to avoid confusion, the terms used here are "pickling" and "unpickling".

Warning

The `pickle` module **is not secure**. Only unpickle data you trust.

It is possible to construct malicious pickle data which will **execute arbitrary code during unpickling**. Never unpickle data that could have come from an untrusted source, or that could have been tampered with.

Consider signing data with *hmac* if you need to ensure that it has not been tampered with.

Safer serialization formats such as *json* may be more appropriate if you are processing untrusted data. See *Comparison with json*.

12.1.1 Relationship to other Python modules

Comparison with marshal

Python has a more primitive serialization module called *marshal*, but in general *pickle* should always be the preferred way to serialize Python objects. *marshal* exists primarily to support Python's `.pyc` files.

The *pickle* module differs from *marshal* in several significant ways:

- The *pickle* module keeps track of the objects it has already serialized, so that later references to the same object won't be serialized again. *marshal* doesn't do this.

  This has implications both for recursive objects and object sharing. Recursive objects are objects that contain references to themselves. These are not handled by marshal, and in fact, attempting to marshal recursive objects will crash your Python interpreter. Object sharing happens when there are multiple references to the

[1] Don't confuse this with the *marshal* module

same object in different places in the object hierarchy being serialized. *pickle* stores such objects only once, and ensures that all other references point to the master copy. Shared objects remain shared, which can be very important for mutable objects.

- *marshal* cannot be used to serialize user-defined classes and their instances. *pickle* can save and restore class instances transparently, however the class definition must be importable and live in the same module as when the object was stored.
- The *marshal* serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support `.pyc` files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The *pickle* serialization format is guaranteed to be backwards compatible across Python releases provided a compatible pickle protocol is chosen and pickling and unpickling code deals with Python 2 to Python 3 type differences if your data is crossing that unique breaking change language boundary.

Comparison with `json`

There are fundamental differences between the pickle protocols and JSON (JavaScript Object Notation):

- JSON is a text serialization format (it outputs unicode text, although most of the time it is then encoded to `utf-8`), while pickle is a binary serialization format;
- JSON is human-readable, while pickle is not;
- JSON is interoperable and widely used outside of the Python ecosystem, while pickle is Python-specific;
- JSON, by default, can only represent a subset of the Python built-in types, and no custom classes; pickle can represent an extremely large number of Python types (many of them automatically, by clever usage of Python's introspection facilities; complex cases can be tackled by implementing *specific object APIs*);
- Unlike pickle, deserializing untrusted JSON does not in itself create an arbitrary code execution vulnerability.

See also

The *json* module: a standard library module allowing JSON serialization and deserialization.

12.1.2 Data stream format

The data format used by *pickle* is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as JSON (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the *pickle* data format uses a relatively compact binary representation. If you need optimal size characteristics, you can efficiently *compress* pickled data.

The module *pickletools* contains tools for analyzing data streams generated by *pickle*. *pickletools* source code has extensive comments about opcodes used by pickle protocols.

There are currently 6 different protocols which can be used for pickling. The higher the protocol used, the more recent the version of Python needed to read the pickle produced.

- Protocol version 0 is the original "human-readable" protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is an old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of *new-style classes*. Refer to **PEP 307** for information about improvements brought by protocol 2.
- Protocol version 3 was added in Python 3.0. It has explicit support for *bytes* objects and cannot be unpickled by Python 2.x. This was the default protocol in Python 3.0–3.7.
- Protocol version 4 was added in Python 3.4. It adds support for very large objects, pickling more kinds of objects, and some data format optimizations. It is the default protocol starting with Python 3.8. Refer to **PEP 3154** for information about improvements brought by protocol 4.

- Protocol version 5 was added in Python 3.8. It adds support for out-of-band data and speedup for in-band data. Refer to **PEP 574** for information about improvements brought by protocol 5.

> **Note**
>
> Serialization is a more primitive notion than persistence; although `pickle` reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The `pickle` module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The `shelve` module provides a simple interface to pickle and unpickle objects on DBM-style database files.

12.1.3 Module Interface

To serialize an object hierarchy, you simply call the `dumps()` function. Similarly, to de-serialize a data stream, you call the `loads()` function. However, if you want more control over serialization and de-serialization, you can create a `Pickler` or an `Unpickler` object, respectively.

The `pickle` module provides the following constants:

`pickle.`**`HIGHEST_PROTOCOL`**

An integer, the highest *protocol version* available. This value can be passed as a *protocol* value to functions `dump()` and `dumps()` as well as the `Pickler` constructor.

`pickle.`**`DEFAULT_PROTOCOL`**

An integer, the default *protocol version* used for pickling. May be less than `HIGHEST_PROTOCOL`. Currently the default protocol is 4, first introduced in Python 3.4 and incompatible with previous versions.

Changed in version 3.0: The default protocol is 3.

Changed in version 3.8: The default protocol is 4.

The `pickle` module provides the following functions to make the pickling process more convenient:

`pickle.`**`dump`**(*obj*, *file*, *protocol=None*, ***, *fix_imports=True*, *buffer_callback=None*)

Write the pickled representation of the object *obj* to the open *file object* *file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

Arguments *file*, *protocol*, *fix_imports* and *buffer_callback* have the same meaning as in the `Pickler` constructor.

Changed in version 3.8: The *buffer_callback* argument was added.

`pickle.`**`dumps`**(*obj*, *protocol=None*, ***, *fix_imports=True*, *buffer_callback=None*)

Return the pickled representation of the object *obj* as a `bytes` object, instead of writing it to a file.

Arguments *protocol*, *fix_imports* and *buffer_callback* have the same meaning as in the `Pickler` constructor.

Changed in version 3.8: The *buffer_callback* argument was added.

`pickle.`**`load`**(*file*, ***, *fix_imports=True*, *encoding='ASCII'*, *errors='strict'*, *buffers=None*)

Read the pickled representation of an object from the open *file object* *file* and return the reconstituted object hierarchy specified therein. This is equivalent to `Unpickler(file).load()`.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *file*, *fix_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the `Unpickler` constructor.

Changed in version 3.8: The *buffers* argument was added.

pickle.**loads**(*data*, */*, ***, *fix_imports=True*, *encoding='ASCII'*, *errors='strict'*, *buffers=None*)

Return the reconstituted object hierarchy of the pickled representation *data* of an object. *data* must be a *bytes-like object*.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *fix_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the *Unpickler* constructor.

Changed in version 3.8: The *buffers* argument was added.

The *pickle* module defines three exceptions:

exception pickle.**PickleError**

Common base class for the other pickling exceptions. It inherits from *Exception*.

exception pickle.**PicklingError**

Error raised when an unpicklable object is encountered by *Pickler*. It inherits from *PickleError*.

Refer to *What can be pickled and unpickled?* to learn what kinds of objects can be pickled.

exception pickle.**UnpicklingError**

Error raised when there is a problem unpickling an object, such as a data corruption or a security violation. It inherits from *PickleError*.

Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) AttributeError, EOFError, ImportError, and IndexError.

The *pickle* module exports three classes, *Pickler*, *Unpickler* and *PickleBuffer*:

class pickle.**Pickler**(*file*, *protocol=None*, ***, *fix_imports=True*, *buffer_callback=None*)

This takes a binary file for writing a pickle data stream.

The optional *protocol* argument, an integer, tells the pickler to use the given protocol; supported protocols are 0 to *HIGHEST_PROTOCOL*. If not specified, the default is *DEFAULT_PROTOCOL*. If a negative number is specified, *HIGHEST_PROTOCOL* is selected.

The *file* argument must have a write() method that accepts a single bytes argument. It can thus be an on-disk file opened for binary writing, an *io.BytesIO* instance, or any other custom object that meets this interface.

If *fix_imports* is true and *protocol* is less than 3, pickle will try to map the new Python 3 names to the old module names used in Python 2, so that the pickle data stream is readable with Python 2.

If *buffer_callback* is `None` (the default), buffer views are serialized into *file* as part of the pickle stream.

If *buffer_callback* is not `None`, then it can be called any number of times with a buffer view. If the callback returns a false value (such as `None`), the given buffer is *out-of-band*; otherwise the buffer is serialized in-band, i.e. inside the pickle stream.

It is an error if *buffer_callback* is not `None` and *protocol* is `None` or smaller than 5.

Changed in version 3.8: The *buffer_callback* argument was added.

dump(*obj*)

Write the pickled representation of *obj* to the open file object given in the constructor.

persistent_id(*obj*)

Do nothing by default. This exists so a subclass can override it.

If *persistent_id()* returns `None`, *obj* is pickled as usual. Any other value causes *Pickler* to emit the returned value as a persistent ID for *obj*. The meaning of this persistent ID should be defined by *Unpickler.persistent_load()*. Note that the value returned by *persistent_id()* cannot itself have a persistent ID.

See *Persistence of External Objects* for details and examples of uses.

Changed in version 3.13: Add the default implementation of this method in the C implementation of `Pickler`.

dispatch_table

A pickler object's dispatch table is a registry of *reduction functions* of the kind which can be declared using `copyreg.pickle()`. It is a mapping whose keys are classes and whose values are reduction functions. A reduction function takes a single argument of the associated class and should conform to the same interface as a `__reduce__()` method.

By default, a pickler object will not have a `dispatch_table` attribute, and it will instead use the global dispatch table managed by the `copyreg` module. However, to customize the pickling for a specific pickler object one can set the `dispatch_table` attribute to a dict-like object. Alternatively, if a subclass of `Pickler` has a `dispatch_table` attribute then this will be used as the default dispatch table for instances of that class.

See *Dispatch Tables* for usage examples.

Added in version 3.3.

reducer_override(*obj*)

Special reducer that can be defined in `Pickler` subclasses. This method has priority over any reducer in the `dispatch_table`. It should conform to the same interface as a `__reduce__()` method, and can optionally return `NotImplemented` to fallback on `dispatch_table`-registered reducers to pickle `obj`.

For a detailed example, see *Custom Reduction for Types, Functions, and Other Objects*.

Added in version 3.8.

fast

Deprecated. Enable fast mode if set to a true value. The fast mode disables the usage of memo, therefore speeding the pickling process by not generating superfluous PUT opcodes. It should not be used with self-referential objects, doing otherwise will cause `Pickler` to recurse infinitely.

Use `pickletools.optimize()` if you need more compact pickles.

class pickle.**Unpickler**(*file*, ***, *fix_imports=True*, *encoding='ASCII'*, *errors='strict'*, *buffers=None*)

This takes a binary file for reading a pickle data stream.

The protocol version of the pickle is detected automatically, so no protocol argument is needed.

The argument *file* must have three methods, a read() method that takes an integer argument, a readinto() method that takes a buffer argument and a readline() method that requires no arguments, as in the `io.BufferedIOBase` interface. Thus *file* can be an on-disk file opened for binary reading, an `io.BytesIO` object, or any other custom object that meets this interface.

The optional arguments *fix_imports*, *encoding* and *errors* are used to control compatibility support for pickle stream generated by Python 2. If *fix_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to 'ASCII' and 'strict', respectively. The *encoding* can be 'bytes' to read these 8-bit string instances as bytes objects. Using `encoding='latin1'` is required for unpickling NumPy arrays and instances of `datetime`, `date` and `time` pickled by Python 2.

If *buffers* is `None` (the default), then all data necessary for deserialization must be contained in the pickle stream. This means that the *buffer_callback* argument was `None` when a `Pickler` was instantiated (or when `dump()` or `dumps()` was called).

If *buffers* is not `None`, it should be an iterable of buffer-enabled objects that is consumed each time the pickle stream references an *out-of-band* buffer view. Such buffers have been given in order to the *buffer_callback* of a Pickler object.

Changed in version 3.8: The *buffers* argument was added.

load()

Read the pickled representation of an object from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein. Bytes past the pickled representation of the object are ignored.

persistent_load(*pid*)

Raise an *UnpicklingError* by default.

If defined, *persistent_load()* should return the object specified by the persistent ID *pid*. If an invalid persistent ID is encountered, an *UnpicklingError* should be raised.

See *Persistence of External Objects* for details and examples of uses.

Changed in version 3.13: Add the default implementation of this method in the C implementation of `Unpickler`.

find_class(*module*, *name*)

Import *module* if necessary and return the object called *name* from it, where the *module* and *name* arguments are *str* objects. Note, unlike its name suggests, *find_class()* is also used for finding functions.

Subclasses may override this to gain control over what type of objects and how they can be loaded, potentially reducing security risks. Refer to *Restricting Globals* for details.

Raises an *auditing event* `pickle.find_class` with arguments `module`, `name`.

class pickle.**PickleBuffer**(*buffer*)

A wrapper for a buffer representing picklable data. *buffer* must be a buffer-providing object, such as a *bytes-like object* or a N-dimensional array.

PickleBuffer is itself a buffer provider, therefore it is possible to pass it to other APIs expecting a buffer-providing object, such as *memoryview*.

PickleBuffer objects can only be serialized using pickle protocol 5 or higher. They are eligible for *out-of-band serialization*.

Added in version 3.8.

raw()

Return a *memoryview* of the memory area underlying this buffer. The returned object is a one-dimensional, C-contiguous memoryview with format `B` (unsigned bytes). *BufferError* is raised if the buffer is neither C- nor Fortran-contiguous.

release()

Release the underlying buffer exposed by the PickleBuffer object.

12.1.4 What can be pickled and unpickled?

The following types can be pickled:

- built-in constants (`None`, `True`, `False`, `Ellipsis`, and *NotImplemented*);
- integers, floating-point numbers, complex numbers;
- strings, bytes, bytearrays;
- tuples, lists, sets, and dictionaries containing only picklable objects;
- functions (built-in and user-defined) accessible from the top level of a module (using `def`, not `lambda`);
- classes accessible from the top level of a module;
- instances of such classes whose the result of calling *__getstate__()* is picklable (see section *Pickling Class Instances* for details).

Attempts to pickle unpicklable objects will raise the *PicklingError* exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure

may exceed the maximum recursion depth, a *RecursionError* will be raised in this case. You can carefully raise this limit with *sys.setrecursionlimit()*.

Note that functions (built-in and user-defined) are pickled by fully *qualified name*, not by value.[2] This means that only the function name is pickled, along with the name of the containing module and classes. Neither the function's code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised.[3]

Similarly, classes are pickled by fully qualified name, so the same restrictions in the unpickling environment apply. Note that none of the class's code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment:

```
class Foo:
    attr = 'A class attribute'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined at the top level of a module.

Similarly, when class instances are pickled, their class's code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions can be made by the class's *__setstate__()* method.

12.1.5 Pickling Class Instances

In this section, we describe the general mechanisms available to you to define, customize, and control how class instances are pickled and unpickled.

In most cases, no additional code is needed to make instances picklable. By default, pickle will retrieve the class and the attributes of an instance via introspection. When a class instance is unpickled, its `__init__()` method is usually *not* invoked. The default behaviour first creates an uninitialized instance and then restores the saved attributes. The following code shows an implementation of this behaviour:

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def restore(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

Classes can alter the default behaviour by providing one or several special methods:

`object.`**`__getnewargs_ex__`**`()`

In protocols 2 and newer, classes that implements the *__getnewargs_ex__()* method can dictate the values passed to the `__new__()` method upon unpickling. The method must return a pair `(args, kwargs)` where *args* is a tuple of positional arguments and *kwargs* a dictionary of named arguments for constructing the object. Those will be passed to the `__new__()` method upon unpickling.

You should implement this method if the `__new__()` method of your class requires keyword-only arguments. Otherwise, it is recommended for compatibility to implement *__getnewargs__()*.

Changed in version 3.6: *__getnewargs_ex__()* is now used in protocols 2 and 3.

`object.`**`__getnewargs__`**`()`

This method serves a similar purpose as *__getnewargs_ex__()*, but supports only positional arguments. It must return a tuple of arguments `args` which will be passed to the `__new__()` method upon unpickling.

[2] This is why `lambda` functions cannot be pickled: all `lambda` functions share the same name: `<lambda>`.
[3] The exception raised will likely be an *ImportError* or an *AttributeError* but it could be something else.

__getnewargs__() will not be called if *__getnewargs_ex__()* is defined.

Changed in version 3.6: Before Python 3.6, *__getnewargs__()* was called instead of *__getnewargs_ex__()* in protocols 2 and 3.

object.**__getstate__**()

Classes can further influence how their instances are pickled by overriding the method *__getstate__()*. It is called and the returned object is pickled as the contents for the instance, instead of a default state. There are several cases:

- For a class that has no instance `__dict__` and no `__slots__`, the default state is `None`.
- For a class that has an instance `__dict__` and no `__slots__`, the default state is `self.__dict__`.
- For a class that has an instance `__dict__` and `__slots__`, the default state is a tuple consisting of two dictionaries: `self.__dict__`, and a dictionary mapping slot names to slot values. Only slots that have a value are included in the latter.
- For a class that has `__slots__` and no instance `__dict__`, the default state is a tuple whose first item is `None` and whose second item is a dictionary mapping slot names to slot values described in the previous bullet.

Changed in version 3.11: Added the default implementation of the `__getstate__()` method in the *object* class.

object.**__setstate__**(*state*)

Upon unpickling, if the class defines *__setstate__()*, it is called with the unpickled state. In that case, there is no requirement for the state object to be a dictionary. Otherwise, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary.

> **Note**
>
> If *__reduce__()* returns a state with value `None` at pickling, the *__setstate__()* method will not be called upon unpickling.

Refer to the section *Handling Stateful Objects* for more information about how to use the methods *__getstate__()* and *__setstate__()*.

> **Note**
>
> At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement `__new__()` to establish such an invariant, as `__init__()` is not called when unpickling an instance.

As we shall see, pickle does not use directly the methods described above. In fact, these methods are part of the copy protocol which implements the *__reduce__()* special method. The copy protocol provides a unified interface for retrieving the data necessary for pickling and copying objects.[4]

Although powerful, implementing *__reduce__()* directly in your classes is error prone. For this reason, class designers should use the high-level interface (i.e., *__getnewargs_ex__()*, *__getstate__()* and *__setstate__()*) whenever possible. We will show, however, cases where using `__reduce__()` is the only option or leads to more efficient pickling or both.

object.**__reduce__**()

The interface is currently defined as follows. The *__reduce__()* method takes no argument and shall return either a string or preferably a tuple (the returned object is often referred to as the "reduce value").

If a string is returned, the string should be interpreted as the name of a global variable. It should be the object's local name relative to its module; the pickle module searches the module namespace to determine the object's module. This behaviour is typically useful for singletons.

[4] The *copy* module uses this protocol for shallow and deep copying operations.

When a tuple is returned, it must be between two and six items long. Optional items can either be omitted, or `None` can be provided as their value. The semantics of each item are in order:

- A callable object that will be called to create the initial version of the object.
- A tuple of arguments for the callable object. An empty tuple must be given if the callable does not accept any argument.
- Optionally, the object's state, which will be passed to the object's *`__setstate__()`* method as previously described. If the object has no such method then, the value must be a dictionary and it will be added to the object's `__dict__` attribute.
- Optionally, an iterator (and not a sequence) yielding successive items. These items will be appended to the object either using `obj.append(item)` or, in batch, using `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have *append and extend methods* with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive key-value pairs. These items will be stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.
- Optionally, a callable with a `(obj, state)` signature. This callable allows the user to programmatically control the state-updating behavior of a specific object, instead of using `obj`'s static *`__setstate__()`* method. If not `None`, this callable will have priority over `obj`'s *`__setstate__()`*.

  Added in version 3.8: The optional sixth tuple item, `(obj, state)`, was added.

`object.`**`__reduce_ex__`**(*protocol*)

Alternatively, a *`__reduce_ex__()`* method may be defined. The only difference is this method should take a single integer argument, the protocol version. When defined, pickle will prefer it over the *`__reduce__()`* method. In addition, *`__reduce__()`* automatically becomes a synonym for the extended version. The main use for this method is to provide backwards-compatible reduce values for older Python releases.

Persistence of External Objects

For the benefit of object persistence, the *`pickle`* module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a persistent ID, which should be either a string of alphanumeric characters (for protocol 0)[5] or just an arbitrary object (for any newer protocol).

The resolution of such persistent IDs is not defined by the *`pickle`* module; it will delegate this resolution to the user-defined methods on the pickler and unpickler, *`persistent_id()`* and *`persistent_load()`* respectively.

To pickle objects that have an external persistent ID, the pickler must have a custom *`persistent_id()`* method that takes an object as an argument and returns either `None` or the persistent ID for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent ID string is returned, the pickler will pickle that object, along with a marker so that the unpickler will recognize it as a persistent ID.

To unpickle external objects, the unpickler must have a custom *`persistent_load()`* method that takes a persistent ID object and returns the referenced object.

Here is a comprehensive example presenting how persistent ID can be used to pickle external objects by reference.

```
# Simple example presenting how persistent ID can be used to pickle
# external objects by reference.

import pickle
import sqlite3
from collections import namedtuple
```

(continues on next page)

[5] The limitation on alphanumeric characters is due to the fact that persistent IDs in protocol 0 are delimited by the newline character. Therefore if any kind of newline characters occurs in persistent IDs, the resulting pickled data will become unreadable.

(continued from previous page)

```
# Simple class representing a record in our database.
MemoRecord = namedtuple("MemoRecord", "key, task")

class DBPickler(pickle.Pickler):

    def persistent_id(self, obj):
        # Instead of pickling MemoRecord as a regular class instance, we emit a
        # persistent ID.
        if isinstance(obj, MemoRecord):
            # Here, our persistent ID is simply a tuple, containing a tag and a
            # key, which refers to a specific record in the database.
            return ("MemoRecord", obj.key)
        else:
            # If obj does not have a persistent ID, return None. This means obj
            # needs to be pickled as usual.
            return None

class DBUnpickler(pickle.Unpickler):

    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection

    def persistent_load(self, pid):
        # This method is invoked whenever a persistent ID is encountered.
        # Here, pid is the tuple returned by DBPickler.
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
            # Fetch the referenced record from the database and return it.
            cursor.execute("SELECT * FROM memos WHERE key=?", (str(key_id),))
            key, task = cursor.fetchone()
            return MemoRecord(key, task)
        else:
            # Always raises an error if you cannot return the correct object.
            # Otherwise, the unpickler will think None is the object referenced
            # by the persistent ID.
            raise pickle.UnpicklingError("unsupported persistent object")

def main():
    import io
    import pprint

    # Initialize and populate our database.
    conn = sqlite3.connect(":memory:")
    cursor = conn.cursor()
    cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
    tasks = (
        'give food to fish',
        'prepare group meeting',
        'fight with a zebra',
        )
    for task in tasks:
        cursor.execute("INSERT INTO memos VALUES(NULL, ?)", (task,))
```

(continues on next page)

(continued from previous page)

```
    # Fetch the records to be pickled.
    cursor.execute("SELECT * FROM memos")
    memos = [MemoRecord(key, task) for key, task in cursor]
    # Save the records using our custom DBPickler.
    file = io.BytesIO()
    DBPickler(file).dump(memos)

    print("Pickled records:")
    pprint.pprint(memos)

    # Update a record, just for good measure.
    cursor.execute("UPDATE memos SET task='learn italian' WHERE key=1")

    # Load the records from the pickle data stream.
    file.seek(0)
    memos = DBUnpickler(file, conn).load()

    print("Unpickled records:")
    pprint.pprint(memos)

if __name__ == '__main__':
    main()
```

Dispatch Tables

If one wants to customize pickling of some classes without disturbing any other code which depends on pickling, then one can create a pickler with a private dispatch table.

The global dispatch table managed by the *copyreg* module is available as `copyreg.dispatch_table`. Therefore, one may choose to use a modified copy of `copyreg.dispatch_table` as a private dispatch table.

For example

```
f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass
```

creates an instance of *pickle.Pickler* with a private dispatch table which handles the `SomeClass` class specially. Alternatively, the code

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

does the same but all instances of `MyPickler` will by default share the private dispatch table. On the other hand, the code

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

modifies the global dispatch table shared by all users of the *copyreg* module.

Handling Stateful Objects

Here's an example that shows how to modify pickling behavior for a class. The `TextReader` class below opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
class TextReader:
    """Print and number lines in a text file."""

    def __init__(self, filename):
        self.filename = filename
        self.file = open(filename)
        self.lineno = 0

    def readline(self):
        self.lineno += 1
        line = self.file.readline()
        if not line:
            return None
        if line.endswith('\n'):
            line = line[:-1]
        return "%i: %s" % (self.lineno, line)

    def __getstate__(self):
        # Copy the object's state from self.__dict__ which contains
        # all our instance attributes. Always use the dict.copy()
        # method to avoid modifying the original state.
        state = self.__dict__.copy()
        # Remove the unpicklable entries.
        del state['file']
        return state

    def __setstate__(self, state):
        # Restore instance attributes (i.e., filename and lineno).
        self.__dict__.update(state)
        # Restore the previously opened file's state. To do so, we need to
        # reopen it and read from it until the line count is restored.
        file = open(self.filename)
        for _ in range(self.lineno):
            file.readline()
        # Finally, save the file.
        self.file = file
```

A sample usage might be something like this:

```
>>> reader = TextReader("hello.txt")
>>> reader.readline()
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'
```

12.1.6 Custom Reduction for Types, Functions, and Other Objects

Added in version 3.8.

Sometimes, *dispatch_table* may not be flexible enough. In particular we may want to customize pickling based on another criterion than the object's type, or we may want to customize the pickling of functions and classes.

For those cases, it is possible to subclass from the *Pickler* class and implement a *reducer_override()* method. This method can return an arbitrary reduction tuple (see *__reduce__()*). It can alternatively return *NotImplemented* to fallback to the traditional behavior.

If both the *dispatch_table* and *reducer_override()* are defined, then *reducer_override()* method takes priority.

> **Note**
>
> For performance reasons, *reducer_override()* may not be called for the following objects: `None`, `True`, `False`, and exact instances of *int*, *float*, *bytes*, *str*, *dict*, *set*, *frozenset*, *list* and *tuple*.

Here is a simple example where we allow pickling and reconstructing a given class:

```
import io
import pickle

class MyClass:
    my_attribute = 1

class MyPickler(pickle.Pickler):
    def reducer_override(self, obj):
        """Custom reducer for MyClass."""
        if getattr(obj, "__name__", None) == "MyClass":
            return type, (obj.__name__, obj.__bases__,
                          {'my_attribute': obj.my_attribute})
        else:
            # For any other object, fallback to usual reduction
            return NotImplemented

f = io.BytesIO()
p = MyPickler(f)
p.dump(MyClass)

del MyClass

unpickled_class = pickle.loads(f.getvalue())

assert isinstance(unpickled_class, type)
assert unpickled_class.__name__ == "MyClass"
assert unpickled_class.my_attribute == 1
```

12.1.7 Out-of-band Buffers

Added in version 3.8.

In some contexts, the *pickle* module is used to transfer massive amounts of data. Therefore, it can be important to minimize the number of memory copies, to preserve performance and resource consumption. However, normal operation of the *pickle* module, as it transforms a graph-like structure of objects into a sequential stream of bytes, intrinsically involves copying data to and from the pickle stream.

This constraint can be eschewed if both the *provider* (the implementation of the object types to be transferred) and the *consumer* (the implementation of the communications system) support the out-of-band transfer facilities provided

by pickle protocol 5 and higher.

Provider API

The large data objects to be pickled must implement a *__reduce_ex__()* method specialized for protocol 5 and higher, which returns a *PickleBuffer* instance (instead of e.g. a *bytes* object) for any large data.

A *PickleBuffer* object *signals* that the underlying buffer is eligible for out-of-band data transfer. Those objects remain compatible with normal usage of the *pickle* module. However, consumers can also opt-in to tell *pickle* that they will handle those buffers by themselves.

Consumer API

A communications system can enable custom handling of the *PickleBuffer* objects generated when serializing an object graph.

On the sending side, it needs to pass a *buffer_callback* argument to *Pickler* (or to the *dump()* or *dumps()* function), which will be called with each *PickleBuffer* generated while pickling the object graph. Buffers accumulated by the *buffer_callback* will not see their data copied into the pickle stream, only a cheap marker will be inserted.

On the receiving side, it needs to pass a *buffers* argument to *Unpickler* (or to the *load()* or *loads()* function), which is an iterable of the buffers which were passed to *buffer_callback*. That iterable should produce buffers in the same order as they were passed to *buffer_callback*. Those buffers will provide the data expected by the reconstructors of the objects whose pickling produced the original *PickleBuffer* objects.

Between the sending side and the receiving side, the communications system is free to implement its own transfer mechanism for out-of-band buffers. Potential optimizations include the use of shared memory or datatype-dependent compression.

Example

Here is a trivial example where we implement a *bytearray* subclass able to participate in out-of-band buffer pickling:

```
class ZeroCopyByteArray(bytearray):

    def __reduce_ex__(self, protocol):
        if protocol >= 5:
            return type(self)._reconstruct, (PickleBuffer(self),), None
        else:
            # PickleBuffer is forbidden with pickle protocols <= 4.
            return type(self)._reconstruct, (bytearray(self),)

    @classmethod
    def _reconstruct(cls, obj):
        with memoryview(obj) as m:
            # Get a handle over the original buffer object
            obj = m.obj
            if type(obj) is cls:
                # Original buffer object is a ZeroCopyByteArray, return it
                # as-is.
                return obj
            else:
                return cls(obj)
```

The reconstructor (the `_reconstruct` class method) returns the buffer's providing object if it has the right type. This is an easy way to simulate zero-copy behaviour on this toy example.

On the consumer side, we can pickle those objects the usual way, which when unserialized will give us a copy of the original object:

```
b = ZeroCopyByteArray(b"abc")
data = pickle.dumps(b, protocol=5)
new_b = pickle.loads(data)
print(b == new_b)  # True
print(b is new_b)  # False: a copy was made
```

But if we pass a *buffer_callback* and then give back the accumulated buffers when unserializing, we are able to get back the original object:

```
b = ZeroCopyByteArray(b"abc")
buffers = []
data = pickle.dumps(b, protocol=5, buffer_callback=buffers.append)
new_b = pickle.loads(data, buffers=buffers)
print(b == new_b)  # True
print(b is new_b)  # True: no copy was made
```

This example is limited by the fact that `bytearray` allocates its own memory: you cannot create a `bytearray` instance that is backed by another object's memory. However, third-party datatypes such as NumPy arrays do not have this limitation, and allow use of zero-copy pickling (or making as few copies as possible) when transferring between distinct processes or systems.

PEP 574 – Pickle protocol 5 with out-of-band data

12.1.8 Restricting Globals

By default, unpickling will import any class or function that it finds in the pickle data. For many applications, this behaviour is unacceptable as it permits the unpickler to import and invoke arbitrary code. Just consider what this hand-crafted pickle data stream does when loaded:

```
>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntR.")
hello world
0
```

In this example, the unpickler imports the `os.system()` function and then apply the string argument "echo hello world". Although this example is inoffensive, it is not difficult to imagine one that could damage your system.

For this reason, you may want to control what gets unpickled by customizing `Unpickler.find_class()`. Unlike its name suggests, `Unpickler.find_class()` is called whenever a global (i.e., a class or a function) is requested. Thus it is possible to either completely forbid globals or restrict them to a safe subset.

Here is an example of an unpickler allowing only few safe classes from the `builtins` module to be loaded:

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}
```

(continues on next page)

(continued from previous page)

```
class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # Only allow safe classes from builtins.
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # Forbid everything else.
        raise pickle.UnpicklingError("global '%s.%s' is forbidden" %
                                     (module, name))

def restricted_loads(s):
    """Helper function analogous to pickle.loads()."""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

A sample usage of our unpickler working as intended:

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'\ntR.")
Traceback (most recent call last):
  ...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...                  b'(S\'getattr(__import__("os"), "system")'
...                  b'("echo hello world")\'\ntR.')
Traceback (most recent call last):
  ...
pickle.UnpicklingError: global 'builtins.eval' is forbidden
```

As our examples shows, you have to be careful with what you allow to be unpickled. Therefore if security is a concern, you may want to consider alternatives such as the marshalling API in *xmlrpc.client* or third-party solutions.

12.1.9 Performance

Recent versions of the pickle protocol (from protocol 2 and upwards) feature efficient binary encodings for several common features and built-in types. Also, the *pickle* module has a transparent optimizer written in C.

12.1.10 Examples

For the simplest code, use the *dump()* and *load()* functions.

```
import pickle

# An arbitrary collection of objects supported by pickle.
data = {
    'a': [1, 2.0, 3+4j],
    'b': ("character string", b"byte string"),
    'c': {None, True, False}
}

with open('data.pickle', 'wb') as f:
    # Pickle the 'data' dictionary using the highest protocol available.
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

The following example reads the resulting pickled data.

```
import pickle

with open('data.pickle', 'rb') as f:
    # The protocol version used is detected automatically, so we do not
    # have to specify it.
    data = pickle.load(f)
```

Indexed databases of objects; uses *pickle*.

Module *copy*
Shallow and deep object copying.

Module *marshal*
High-performance serialization of built-in types.

12.2 copyreg — Register pickle support functions

Source code: Lib/copyreg.py

The *copyreg* module offers a way to define functions used while pickling specific objects. The *pickle* and *copy* modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

copyreg.**constructor**(*object*)

Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises *TypeError*.

copyreg.**pickle**(*type*, *function*, *constructor_ob=None*)

Declares that *function* should be used as a "reduction" function for objects of type *type*. *function* must return either a string or a tuple containing between two and six elements. See the *dispatch_table* for more details on the interface of *function*.

The *constructor_ob* parameter is a legacy feature and is now ignored, but if passed it must be a callable.

Note that the *dispatch_table* attribute of a pickler object or subclass of *pickle.Pickler* can also be used for declaring reduction functions.

12.2.1 Example

The example below would like to show how to register a pickle function and how it will be used:

```
>>> import copyreg, copy, pickle
>>> class C:
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
```

(continues on next page)

(continued from previous page)

```
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

12.3 `shelve` — Python object persistence

Source code: Lib/shelve.py

A "shelf" is a persistent, dictionary-like object. The difference with "dbm" databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects — anything that the *pickle* module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

`shelve.open`(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of *dbm.open()*.

By default, pickles created with *pickle.DEFAULT_PROTOCOL* are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see *Example*). If the optional *writeback* parameter is set to `True`, all entries accessed are also cached in memory, and written back on *sync()* and *close()*; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

Changed in version 3.10: *pickle.DEFAULT_PROTOCOL* is now used as the default pickle protocol.

Changed in version 3.11: Accepts *path-like object* for filename.

Note

Do not rely on the shelf being closed automatically; always call *close()* explicitly when you don't need it any more, or use *shelve.open()* as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

Warning

Because the *shelve* module is backed by *pickle*, it is insecure to load a shelf from an untrusted source. Like with pickle, loading a shelf can execute arbitrary code.

Shelf objects support most of methods and operations supported by dictionaries (except copying, constructors and operators `|` and `|=`). This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

Shelf.**sync**()

Write back all entries in the cache if the shelf was opened with *writeback* set to `True`. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with `close()`.

Shelf.**close**()

Synchronize and close the persistent *dict* object. Operations on a closed shelf will fail with a `ValueError`.

See also

Persistent dictionary recipe with widely supported storage formats and having the speed of native dictionaries.

12.3.1 Restrictions

- The choice of which database package will be used (such as `dbm.ndbm` or `dbm.gnu`) depends on which interface is available. Therefore it is not safe to open the database directly using `dbm`. The database is also (unfortunately) subject to the limitations of `dbm`, if it is used — this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The `shelve` module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.
- On macOS `dbm.ndbm` can silently corrupt the database file on updates, which can cause hard crashes when trying to read from the database.

class shelve.**Shelf**(*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of `collections.abc.MutableMapping` which stores pickled values in the *dict* object.

By default, pickles created with `pickle.DEFAULT_PROTOCOL` are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the `pickle` documentation for a discussion of the pickle protocols.

If the *writeback* parameter is `True`, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

The *keyencoding* parameter is the encoding used to encode keys before they are used with the underlying dict.

A `Shelf` object can also be used as a context manager, in which case it will be automatically closed when the `with` block ends.

Changed in version 3.2: Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

Changed in version 3.4: Added context manager support.

Changed in version 3.10: `pickle.DEFAULT_PROTOCOL` is now used as the default pickle protocol.

class shelve.**BsdDbShelf**(*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of `Shelf` which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` methods. These are available in the third-party `bsddb` module from pybsddb but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the `Shelf` class.

class shelve.**DbfilenameShelf**(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of `Shelf` which accepts a *filename* instead of a dict-like object. The underlying file will be opened using `dbm.open()`. By default, the file will be created and opened for both read and write. The optional

flag parameter has the same interpretation as for the `open()` function. The optional *protocol* and *writeback* parameters have the same interpretation as for the `Shelf` class.

12.3.2 Example

To summarize the interface (`key` is a string, `data` is an arbitrary object):

```
import shelve

d = shelve.open(filename)  # open -- file may get suffix added by low-level
                           # library

d[key] = data              # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]              # retrieve a COPY of data at key (raise KeyError
                           # if no such key)
del d[key]                 # delete data stored at key (raises KeyError
                           # if no such key)

flag = key in d            # true if the key exists
klist = list(d.keys())     # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]        # this works as expected, but...
d['xx'].append(3)          # *this doesn't!* -- d['xx'] is STILL [0, 1, 2]!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']             # extracts the copy
temp.append(5)             # mutates the copy
d['xx'] = temp             # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()                  # close it
```

Module *dbm*
Generic interface to `dbm`-style databases.

Module *pickle*
Object serialization used by `shelve`.

12.4 `marshal` — Internal Python object serialization

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Mac, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does).[1]

[1] The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term "marshalling" for shipping of data around in a self-contained form. Strictly speaking, "to marshal" means to convert some data from internal to external form (in an RPC buffer for instance) and "unmarshalling" for the reverse process.

This is not a general "persistence" module. For general persistence and transfer of Python objects through RPC calls, see the modules *pickle* and *shelve*. The *marshal* module exists mainly to support reading and writing the "pseudo-compiled" code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. The format of code objects is not compatible between Python versions, even if the version of the format is the same. De-serializing a code object in the incorrect Python version has undefined behavior. If you're serializing and de-serializing Python objects, use the *pickle* module instead – the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

Warning

The *marshal* module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, floating-point numbers, complex numbers, strings, bytes, bytearrays, tuples, lists, sets, frozensets, dictionaries, and code objects (if *allow_code* is true), where it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported. The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled. For format *version* lower than 3, recursive lists, sets and dictionaries cannot be written (see below).

There are functions that read/write files as well as functions operating on bytes-like objects.

The module defines these functions:

`marshal.`**`dump`**(*value*, *file*, *version=version*, */*, ***, *allow_code=True*)

Write the value on the open file. The value must be a supported type. The file must be a writeable *binary file*.

If the value has (or contains an object that has) an unsupported type, a *ValueError* exception is raised — but garbage data will also be written to the file. The object will not be properly read back by *load()*. Code objects are only supported if *allow_code* is true.

The *version* argument indicates the data format that `dump` should use (see below).

Raises an *auditing event* `marshal.dumps` with arguments `value`, `version`.

Changed in version 3.13: Added the *allow_code* parameter.

`marshal.`**`load`**(*file*, */*, ***, *allow_code=True*)

Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise *EOFError*, *ValueError* or *TypeError*. Code objects are only supported if *allow_code* is true. The file must be a readable *binary file*.

Raises an *auditing event* `marshal.load` with no arguments.

Note

If an object containing an unsupported type was marshalled with *dump()*, *load()* will substitute `None` for the unmarshallable type.

Changed in version 3.10: This call used to raise a `code.__new__` audit event for each code object. Now it raises a single `marshal.load` event for the entire load operation.

Changed in version 3.13: Added the *allow_code* parameter.

`marshal.`**`dumps`**(*value*, *version=version*, */*, ***, *allow_code=True*)

Return the bytes object that would be written to a file by `dump(value, file)`. The value must be a supported type. Raise a *ValueError* exception if value has (or contains an object that has) an unsupported type. Code objects are only supported if *allow_code* is true.

The *version* argument indicates the data format that `dumps` should use (see below).

Raises an *auditing event* `marshal.dumps` with arguments `value`, `version`.

Changed in version 3.13: Added the *allow_code* parameter.

`marshal.`**`loads`**(*bytes*, */*, ***, *allow_code=True*)

Convert the *bytes-like object* to a value. If no valid value is found, raise *EOFError*, *ValueError* or *TypeError*. Code objects are only supported if *allow_code* is true. Extra bytes in the input are ignored.

Raises an *auditing event* `marshal.loads` with argument `bytes`.

Changed in version 3.10: This call used to raise a `code.__new__` audit event for each code object. Now it raises a single `marshal.loads` event for the entire load operation.

Changed in version 3.13: Added the *allow_code* parameter.

In addition, the following constants are defined:

`marshal.`**`version`**

Indicates the format that the module uses. Version 0 is the historical format, version 1 shares interned strings and version 2 uses a binary format for floating-point numbers. Version 3 adds support for object instancing and recursion. The current version is 4.

12.5 `dbm` — Interfaces to Unix "databases"

Source code: Lib/dbm/__init__.py

---

dbm is a generic interface to variants of the DBM database:

- *dbm.sqlite3*
- *dbm.gnu*
- *dbm.ndbm*

If none of these modules are installed, the slow-but-simple implementation in module *dbm.dumb* will be used. There is a third party interface to the Oracle Berkeley DB.

exception `dbm.`**`error`**

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named *dbm.error* as the first item — the latter is used when *dbm.error* is raised.

`dbm.`**`whichdb`**(*filename*)

This function attempts to guess which of the several simple database modules available — *dbm.sqlite3*, *dbm.gnu*, *dbm.ndbm*, or *dbm.dumb* — should be used to open a given file.

Return one of the following values:

- `None` if the file can't be opened because it's unreadable or doesn't exist
- the empty string (`''`) if the file's format can't be guessed
- a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`

Changed in version 3.11: *filename* accepts a *path-like object*.

`dbm.`**`open`**(*file*, *flag='r'*, *mode=0o666*)

Open a database and return the corresponding database object.

Parameters

- **`file`** (*path-like object*) – The database file to open.

  If the database file already exists, the *whichdb()* function is used to determine its type and the appropriate module is used; if it does not exist, the first submodule listed above that can be imported is used.

- **flag** (str) –
  - 'r' (default): Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c': Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** (int) – The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

Changed in version 3.11: *file* accepts a *path-like object*.

The object returned by *open()* supports the same basic functionality as a *dict*; keys and their corresponding values can be stored, retrieved, and deleted, and the in operator and the keys() method are available, as well as get() and setdefault() methods.

Key and values are always stored as *bytes*. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a with statement, which will automatically close them when done.

Changed in version 3.2: get() and setdefault() methods are now available for all *dbm* backends.

Changed in version 3.4: Added native support for the context management protocol to the objects returned by *open()*.

Changed in version 3.8: Deleting a key from a read-only database raises a database module specific exception instead of *KeyError*.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'

    # Note that the keys are considered bytes now.
    assert db[b'www.python.org'] == b'Python Website'
    # Notice how the value is now in bytes.
    assert db['www.cnn.com'] == b'Cable News Network'

    # Often-used methods of the dict interface work too.
    print(db.get('python.org', b'not present'))

    # Storing a non-string key or value will raise an exception (most
    # likely a TypeError).
    db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement.
```

See also

Module *shelve*
Persistence module which stores non-string data.

The individual submodules are described in the following sections.

12.5.1 dbm.sqlite3 — SQLite backend for dbm

Added in version 3.13.

Source code: Lib/dbm/sqlite3.py

This module uses the standard library *sqlite3* module to provide an SQLite backend for the *dbm* module. The files created by *dbm.sqlite3* can thus be opened by *sqlite3*, or any other SQLite browser, including the SQLite CLI.

Availability: not WASI.

This module does not work or is not available on WebAssembly. See *WebAssembly platforms* for more information.

dbm.sqlite3.**open**(*filename*, */*, *flag='r'*, *mode=0o666*)

Open an SQLite database. The returned object behaves like a *mapping*, implements a `close()` method, and supports a "closing" context manager via the `with` keyword.

Parameters

- **filename** (*path-like object*) – The path to the database to be opened.
- **flag** (`str`) –
  - `'r'` (default): Open existing database for reading only.
  - `'w'`: Open existing database for reading and writing.
  - `'c'`: Open database for reading and writing, creating it if it doesn't exist.
  - `'n'`: Always create a new, empty database, open for reading and writing.
- **mode** – The Unix file access mode of the file (default: octal `0o666`), used only when the database has to be created.

12.5.2 dbm.gnu — GNU database manager

Source code: Lib/dbm/gnu.py

The *dbm.gnu* module provides an interface to the GDBM (GNU dbm) library, similar to the *dbm.ndbm* module, but with additional functionality like crash tolerance.

> **Note**
>
> The file formats created by *dbm.gnu* and *dbm.ndbm* are incompatible and can not be used interchangeably.

Availability: not Android, not iOS, not WASI.

This module is not supported on *mobile platforms* or *WebAssembly platforms*.

exception dbm.gnu.**error**

Raised on *dbm.gnu*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.gnu.**open**(*filename*, *flag='r'*, *mode=0o666*, */*)

Open a GDBM database and return a `gdbm` object.

Parameters

- **filename** (*path-like object*) – The database file to open.
- **flag** (`str`) –

- `'r'` (default): Open existing database for reading only.
- `'w'`: Open existing database for reading and writing.
- `'c'`: Open database for reading and writing, creating it if it doesn't exist.
- `'n'`: Always create a new, empty database, open for reading and writing.

The following additional characters may be appended to control how the database is opened:

- `'f'`: Open the database in fast mode. Writes to the database will not be synchronized.
- `'s'`: Synchronized mode. Changes to the database will be written immediately to the file.
- `'u'`: Do not lock database.

Not all flags are valid for all versions of GDBM. See the *open_flags* member for a list of supported flag characters.

- **mode** (`int`) – The Unix file access mode of the file (default: octal `0o666`), used only when the database has to be created.

Raises

error – If an invalid *flag* argument is passed.

Changed in version 3.11: *filename* accepts a *path-like object*.

dbm.gnu.**open_flags**

A string of characters the *flag* parameter of *open()* supports.

gdbm objects behave similar to *mappings*, but `items()` and `values()` methods are not supported. The following methods are also provided:

gdbm.**firstkey**()

It's possible to loop over every key in the database using this method and the *nextkey()* method. The traversal is ordered by GDBM's internal hash values, and won't be sorted by the key values. This method returns the starting key.

gdbm.**nextkey**(*key*)

Returns the key that follows *key* in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k is not None:
    print(k)
    k = db.nextkey(k)
```

gdbm.**reorganize**()

If you have carried out a lot of deletions and would like to shrink the space used by the GDBM file, this routine will reorganize the database. gdbm objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

gdbm.**sync**()

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

gdbm.**close**()

Close the GDBM database.

gdbm.**clear**()

Remove all items from the GDBM database.

Added in version 3.13.

12.5.3 dbm.ndbm — New Database Manager

Source code: Lib/dbm/ndbm.py

The *dbm.ndbm* module provides an interface to the NDBM (New Database Manager) library. This module can be used with the "classic" NDBM interface or the GDBM compatibility interface.

Note

The file formats created by *dbm.gnu* and *dbm.ndbm* are incompatible and can not be used interchangeably.

Warning

The NDBM library shipped as part of macOS has an undocumented limitation on the size of values, which can result in corrupted database files when storing values larger than this limit. Reading such corrupted files can result in a hard crash (segmentation fault).

Availability: not Android, not iOS, not WASI.

This module is not supported on *mobile platforms* or *WebAssembly platforms*.

exception dbm.ndbm.**error**

Raised on *dbm.ndbm*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.ndbm.**library**

Name of the NDBM implementation library used.

dbm.ndbm.**open**(*filename*, *flag='r'*, *mode=0o666*, */*)

Open an NDBM database and return an ndbm object.

Parameters

- **filename** (*path-like object*) – The basename of the database file (without the .dir or .pag extensions).
- **flag** (str) –
  - 'r' (default): Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c': Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** (int) – The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

ndbm objects behave similar to *mappings*, but items() and values() methods are not supported. The following methods are also provided:

Changed in version 3.11: Accepts *path-like object* for filename.

ndbm.**close**()

Close the NDBM database.

ndbm.**clear**()

Remove all items from the NDBM database.

Added in version 3.13.

12.5.4 dbm.dumb — Portable DBM implementation

Source code: Lib/dbm/dumb.py

> **Note**
>
> The *dbm.dumb* module is intended as a last resort fallback for the *dbm* module when a more robust module is not available. The *dbm.dumb* module is not written for speed and is not nearly as heavily used as the other database modules.

The *dbm.dumb* module provides a persistent *dict*-like interface which is written entirely in Python. Unlike other *dbm* backends, such as *dbm.gnu*, no external library is required.

The dbm.dumb module defines the following:

exception dbm.dumb.**error**

Raised on *dbm.dumb*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.dumb.**open**(*filename*, *flag='c'*, *mode=0o666*)

Open a dbm.dumb database. The returned database object behaves similar to a *mapping*, in addition to providing *sync()* and *close()* methods.

Parameters

- **filename** – The basename of the database file (without extensions). A new database creates the following files:
  - *filename*.dat
  - *filename*.dir
- **flag** (str) –
  - 'r': Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c' (default): Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** (int) – The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

> **Warning**
>
> It is possible to crash the Python interpreter when loading a database with a sufficiently large/complex entry due to stack depth limitations in Python's AST compiler.

Changed in version 3.5: *open()* always creates a new database when *flag* is 'n'.

Changed in version 3.8: A database opened read-only if *flag* is 'r'. A database is not created if it does not exist if *flag* is 'r' or 'w'.

Changed in version 3.11: *filename* accepts a *path-like object*.

In addition to the methods provided by the *collections.abc.MutableMapping* class, the following methods are provided:

dumbdbm.**sync**()

Synchronize the on-disk directory and data files. This method is called by the *shelve.Shelf.sync()* method.

dumbdbm.**close**()

Close the database.

12.6 sqlite3 — DB-API 2.0 interface for SQLite databases

Source code: Lib/sqlite3/ SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The sqlite3 module was written by Gerhard Häring. It provides an SQL interface compliant with the DB-API 2.0 specification described by **PEP 249**, and requires SQLite 3.15.2 or newer.

This document includes four main sections:

- *Tutorial* teaches how to use the sqlite3 module.
- *Reference* describes the classes and functions this module defines.
- *How-to guides* details how to handle specific tasks.
- *Explanation* provides in-depth background on transaction control.

PEP 249 - Database API Specification 2.0
PEP written by Marc-André Lemburg.

12.6.1 Tutorial

In this tutorial, you will create a database of Monty Python movies using basic sqlite3 functionality. It assumes a fundamental understanding of database concepts, including cursors and transactions.

First, we need to create a new database and open a database connection to allow sqlite3 to work with it. Call *sqlite3.connect()* to create a connection to the database tutorial.db in the current working directory, implicitly creating it if it does not exist:

```
import sqlite3
con = sqlite3.connect("tutorial.db")
```

The returned *Connection* object con represents the connection to the on-disk database.

In order to execute SQL statements and fetch results from SQL queries, we will need to use a database cursor. Call *con.cursor()* to create the *Cursor*:

```
cur = con.cursor()
```

Now that we've got a database connection and a cursor, we can create a database table movie with columns for title, release year, and review score. For simplicity, we can just use column names in the table declaration – thanks to the flexible typing feature of SQLite, specifying the data types is optional. Execute the CREATE TABLE statement by calling *cur.execute(...)*:

```
cur.execute("CREATE TABLE movie(title, year, score)")
```

We can verify that the new table has been created by querying the `sqlite_master` table built-in to SQLite, which should now contain an entry for the `movie` table definition (see The Schema Table for details). Execute that query by calling *`cur.execute(...)`*, assign the result to `res`, and call *`res.fetchone()`* to fetch the resulting row:

```
>>> res = cur.execute("SELECT name FROM sqlite_master")
>>> res.fetchone()
('movie',)
```

We can see that the table has been created, as the query returns a *`tuple`* containing the table's name. If we query `sqlite_master` for a non-existent table `spam`, `res.fetchone()` will return `None`:

```
>>> res = cur.execute("SELECT name FROM sqlite_master WHERE name='spam'")
>>> res.fetchone() is None
True
```

Now, add two rows of data supplied as SQL literals by executing an `INSERT` statement, once again by calling *`cur.execute(...)`*:

```
cur.execute("""
    INSERT INTO movie VALUES
        ('Monty Python and the Holy Grail', 1975, 8.2),
        ('And Now for Something Completely Different', 1971, 7.5)
""")
```

The `INSERT` statement implicitly opens a transaction, which needs to be committed before changes are saved in the database (see *Transaction control* for details). Call *`con.commit()`* on the connection object to commit the transaction:

```
con.commit()
```

We can verify that the data was inserted correctly by executing a `SELECT` query. Use the now-familiar *`cur.execute(...)`* to assign the result to `res`, and call *`res.fetchall()`* to return all resulting rows:

```
>>> res = cur.execute("SELECT score FROM movie")
>>> res.fetchall()
[(8.2,), (7.5,)]
```

The result is a *`list`* of two `tuple`s, one per row, each containing that row's `score` value.

Now, insert three more rows by calling *`cur.executemany(...)`*:

```
data = [
    ("Monty Python Live at the Hollywood Bowl", 1982, 7.9),
    ("Monty Python's The Meaning of Life", 1983, 7.5),
    ("Monty Python's Life of Brian", 1979, 8.0),
]
cur.executemany("INSERT INTO movie VALUES(?, ?, ?)", data)
con.commit()  # Remember to commit the transaction after executing INSERT.
```

Notice that `?` placeholders are used to bind `data` to the query. Always use placeholders instead of string formatting to bind Python values to SQL statements, to avoid SQL injection attacks (see *How to use placeholders to bind values in SQL queries* for more details).

We can verify that the new rows were inserted by executing a `SELECT` query, this time iterating over the results of the query:

```
>>> for row in cur.execute("SELECT year, title FROM movie ORDER BY year"):
...     print(row)
(1971, 'And Now for Something Completely Different')
(1975, 'Monty Python and the Holy Grail')
```

(continues on next page)

(continued from previous page)

```
(1979, "Monty Python's Life of Brian")
(1982, 'Monty Python Live at the Hollywood Bowl')
(1983, "Monty Python's The Meaning of Life")
```

Each row is a two-item *tuple* of `(year, title)`, matching the columns selected in the query.

Finally, verify that the database has been written to disk by calling *con.close()* to close the existing connection, opening a new one, creating a new cursor, then querying the database:

```
>>> con.close()
>>> new_con = sqlite3.connect("tutorial.db")
>>> new_cur = new_con.cursor()
>>> res = new_cur.execute("SELECT title, year FROM movie ORDER BY score DESC")
>>> title, year = res.fetchone()
>>> print(f'The highest scoring Monty Python movie is {title!r}, released in {year}
↪')
The highest scoring Monty Python movie is 'Monty Python and the Holy Grail',␣
↪released in 1975
>>> new_con.close()
```

You've now created an SQLite database using the `sqlite3` module, inserted data and retrieved values from it in multiple ways.

12.6.2 Reference

Module functions

sqlite3.**connect**(*database*, *timeout=5.0*, *detect_types=0*, *isolation_level='DEFERRED'*, *check_same_thread=True*, *factory=sqlite3.Connection*, *cached_statements=128*, *uri=False*, ***, *autocommit=sqlite3.LEGACY_TRANSACTION_CONTROL*)

Open a connection to an SQLite database.

Parameters

- **database** (*path-like object*) – The path to the database file to be opened. You can pass `":memory:"` to create an SQLite database existing only in memory, and open a connection to it.
- **timeout** (`float`) – How many seconds the connection should wait before raising an *OperationalError* when a table is locked. If another connection opens a transaction to modify a table, that table will be locked until the transaction is committed. Default five seconds.
- **detect_types** (`int`) – Control whether and how data types not *natively supported by SQLite* are looked up to be converted to Python types, using the converters registered with *register_converter()*. Set it to any combination (using `|`, bitwise or) of

PARSE_DECLTYPES and *PARSE_COLNAMES* to enable this. Column names takes precedence over declared types if both flags are set. By default (`0`), type detection is disabled.

- **isolation_level** (`str` | *None*) – Control legacy transaction handling behaviour. See *Connection.isolation_level* and *Transaction control via the isolation_level attribute* for more information. Can be `"DEFERRED"` (default), `"EXCLUSIVE"` or `"IMMEDIATE"`; or `None` to disable opening transactions implicitly. Has no effect unless *Connection.autocommit* is set to *LEGACY_TRANSACTION_CONTROL* (the default).
- **check_same_thread** (`bool`) – If `True` (default), *ProgrammingError* will be raised if the database connection is used by a thread other than the one that created it. If `False`, the connection may be accessed in multiple threads; write operations may need to be serialized by the user to avoid data corruption. See *threadsafety* for more information.
- **factory** (`Connection`) – A custom subclass of *Connection* to create the connection with, if not the default *Connection* class.
- **cached_statements** (`int`) – The number of statements that `sqlite3` should internally cache for this connection, to avoid parsing overhead. By default, 128 statements.
- **uri** (`bool`) – If set to `True`, *database* is interpreted as a URI (Uniform Resource Identifier) with a file path and an optional query string. The scheme part *must* be `"file:"`, and the path can be relative or absolute. The query string allows passing parameters to SQLite, enabling various *How to work with SQLite URIs*.
- **autocommit** (`bool`) – Control **PEP 249** transaction handling behaviour. See *Connection.autocommit* and *Transaction control via the autocommit attribute* for more information. *autocommit* currently defaults to *LEGACY_TRANSACTION_CONTROL*. The default will change to `False` in a future Python release.

Return type
Connection

Raises an *auditing event* `sqlite3.connect` with argument `database`.

Raises an *auditing event* `sqlite3.connect/handle` with argument `connection_handle`.

Changed in version 3.4: Added the *uri* parameter.

Changed in version 3.7: *database* can now also be a *path-like object*, not only a string.

Changed in version 3.10: Added the `sqlite3.connect/handle` auditing event.

Changed in version 3.12: Added the *autocommit* parameter.

Changed in version 3.13: Positional use of the parameters *timeout*, *detect_types*, *isolation_level*, *check_same_thread*, *factory*, *cached_statements*, and *uri* is deprecated. They will become keyword-only parameters in Python 3.15.

`sqlite3.`**complete_statement**(*statement*)

Return `True` if the string *statement* appears to contain one or more complete SQL statements. No syntactic verification or parsing of any kind is performed, other than checking that there are no unclosed string literals and the statement is terminated by a semicolon.

For example:

```
>>> sqlite3.complete_statement("SELECT foo FROM bar;")
True
>>> sqlite3.complete_statement("SELECT foo")
False
```

This function may be useful during command-line input to determine if the entered text seems to form a complete SQL statement, or if additional input is needed before calling *execute()*.

See `runsource()` in Lib/sqlite3/__main__.py for real-world use.

sqlite3.**enable_callback_tracebacks**(*flag*, /)

Enable or disable callback tracebacks. By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to `True`. Afterwards, you will get tracebacks from callbacks on *sys.stderr*. Use `False` to disable the feature again.

> **Note**
>
> Errors in user-defined function callbacks are logged as unraisable exceptions. Use an *unraisable hook handler* for introspection of the failed callback.

sqlite3.**register_adapter**(*type*, *adapter*, /)

Register an *adapter* *callable* to adapt the Python type *type* into an SQLite type. The adapter is called with a Python object of type *type* as its sole argument, and must return a value of a *type that SQLite natively understands*.

sqlite3.**register_converter**(*typename*, *converter*, /)

Register the *converter* *callable* to convert SQLite objects of type *typename* into a Python object of a specific type. The converter is invoked for all SQLite values of type *typename*; it is passed a *bytes* object and should return an object of the desired Python type. Consult the parameter *detect_types* of *connect()* for information regarding how type detection works.

Note: *typename* and the name of the type in your query are matched case-insensitively.

Module constants

sqlite3.**LEGACY_TRANSACTION_CONTROL**

Set *autocommit* to this constant to select old style (pre-Python 3.12) transaction control behaviour. See *Transaction control via the isolation_level attribute* for more information.

sqlite3.**PARSE_DECLTYPES**

Pass this flag value to the *detect_types* parameter of *connect()* to look up a converter function using the declared types for each column. The types are declared when the database table is created. `sqlite3` will look up a converter function using the first word of the declared type as the converter dictionary key. For example:

```
CREATE TABLE test(
   i integer primary key,   ! will look up a converter named "integer"
   p point,                 ! will look up a converter named "point"
   n number(10)             ! will look up a converter named "number"
)
```

This flag may be combined with *PARSE_COLNAMES* using the `|` (bitwise or) operator.

> **Note**
>
> Generated fields (for example `MAX(p)`) are returned as *str*. Use `PARSE_COLNAMES` to enforce types for such queries.

sqlite3.**PARSE_COLNAMES**

Pass this flag value to the *detect_types* parameter of *connect()* to look up a converter function by using the type name, parsed from the query column name, as the converter dictionary key. The query column name must be wrapped in double quotes (`"`) and the type name must be wrapped in square brackets (`[]`).

```
SELECT MAX(p) as "p [point]" FROM test;  ! will look up converter "point"
```

This flag may be combined with *PARSE_DECLTYPES* using the `|` (bitwise or) operator.

sqlite3.**SQLITE_OK**

sqlite3.**SQLITE_DENY**

sqlite3.**SQLITE_IGNORE**

Flags that should be returned by the *authorizer_callback* *callable* passed to *Connection.set_authorizer()*, to indicate whether:

- Access is allowed (SQLITE_OK),
- The SQL statement should be aborted with an error (SQLITE_DENY)
- The column should be treated as a NULL value (SQLITE_IGNORE)

sqlite3.**apilevel**

String constant stating the supported DB-API level. Required by the DB-API. Hard-coded to "2.0".

sqlite3.**paramstyle**

String constant stating the type of parameter marker formatting expected by the sqlite3 module. Required by the DB-API. Hard-coded to "qmark".

> **Note**
>
> The named DB-API parameter style is also supported.

sqlite3.**sqlite_version**

Version number of the runtime SQLite library as a *string*.

sqlite3.**sqlite_version_info**

Version number of the runtime SQLite library as a *tuple* of *integers*.

sqlite3.**threadsafety**

Integer constant required by the DB-API 2.0, stating the level of thread safety the sqlite3 module supports. This attribute is set based on the default threading mode the underlying SQLite library is compiled with. The SQLite threading modes are:

1. **Single-thread**: In this mode, all mutexes are disabled and SQLite is unsafe to use in more than a single thread at once.
2. **Multi-thread**: In this mode, SQLite can be safely used by multiple threads provided that no single database connection is used simultaneously in two or more threads.
3. **Serialized**: In serialized mode, SQLite can be safely used by multiple threads with no restriction.

The mappings from SQLite threading modes to DB-API 2.0 threadsafety levels are as follows:

SQLite threading mode	thread-safety	SQLITE_THREADS/	DB-API 2.0 meaning
single-thread	0	0	Threads may not share the module
multi-thread	1	2	Threads may share the module, but not connections
serialized	3	1	Threads may share the module, connections and cursors

Changed in version 3.11: Set *threadsafety* dynamically instead of hard-coding it to 1.

sqlite3.**version**

Version number of this module as a *string*. This is not the version of the SQLite library.

Deprecated since version 3.12, will be removed in version 3.14: This constant used to reflect the version number of the pysqlite package, a third-party library which used to upstream changes to sqlite3. Today, it carries no meaning or practical value.

sqlite3.**version_info**

Version number of this module as a *tuple* of *integers*. This is not the version of the SQLite library.

Deprecated since version 3.12, will be removed in version 3.14: This constant used to reflect the version number of the `pysqlite` package, a third-party library which used to upstream changes to `sqlite3`. Today, it carries no meaning or practical value.

sqlite3.**SQLITE_DBCONFIG_DEFENSIVE**

sqlite3.**SQLITE_DBCONFIG_DQS_DDL**

sqlite3.**SQLITE_DBCONFIG_DQS_DML**

sqlite3.**SQLITE_DBCONFIG_ENABLE_FKEY**

sqlite3.**SQLITE_DBCONFIG_ENABLE_FTS3_TOKENIZER**

sqlite3.**SQLITE_DBCONFIG_ENABLE_LOAD_EXTENSION**

sqlite3.**SQLITE_DBCONFIG_ENABLE_QPSG**

sqlite3.**SQLITE_DBCONFIG_ENABLE_TRIGGER**

sqlite3.**SQLITE_DBCONFIG_ENABLE_VIEW**

sqlite3.**SQLITE_DBCONFIG_LEGACY_ALTER_TABLE**

sqlite3.**SQLITE_DBCONFIG_LEGACY_FILE_FORMAT**

sqlite3.**SQLITE_DBCONFIG_NO_CKPT_ON_CLOSE**

sqlite3.**SQLITE_DBCONFIG_RESET_DATABASE**

sqlite3.**SQLITE_DBCONFIG_TRIGGER_EQP**

sqlite3.**SQLITE_DBCONFIG_TRUSTED_SCHEMA**

sqlite3.**SQLITE_DBCONFIG_WRITABLE_SCHEMA**

These constants are used for the *Connection.setconfig()* and *getconfig()* methods.

The availability of these constants varies depending on the version of SQLite Python was compiled with.

Added in version 3.12.

https://www.sqlite.org/c3ref/c_dbconfig_defensive.html
SQLite docs: Database Connection Configuration Options

Connection objects

class sqlite3.**Connection**

Each open SQLite database is represented by a `Connection` object, which is created using *sqlite3.connect()*. Their main purpose is creating *Cursor* objects, and *Transaction control*.

See also

- *How to use connection shortcut methods*
- *How to use the connection context manager*

Changed in version 3.13: A *ResourceWarning* is emitted if *close()* is not called before a `Connection` object is deleted.

An SQLite database connection has the following attributes and methods:

cursor(*factory=Cursor*)

Create and return a *Cursor* object. The cursor method accepts a single optional parameter *factory*. If supplied, this must be a *callable* returning an instance of *Cursor* or its subclasses.

blobopen(*table*, *column*, *row*, */*, ***, *readonly=False*, *name='main'*)

Open a *Blob* handle to an existing BLOB (Binary Large OBject).

Parameters

- **table** (str) – The name of the table where the blob is located.
- **column** (str) – The name of the column where the blob is located.
- **row** (str) – The name of the row where the blob is located.
- **readonly** (bool) – Set to `True` if the blob should be opened without write permissions. Defaults to `False`.
- **name** (str) – The name of the database where the blob is located. Defaults to `"main"`.

Raises

OperationalError – When trying to open a blob in a `WITHOUT ROWID` table.

Return type

Blob

> **Note**
>
> The blob size cannot be changed using the *Blob* class. Use the SQL function `zeroblob` to create a blob with a fixed size.

Added in version 3.11.

commit()

Commit any pending transaction to the database. If *autocommit* is `True`, or there is no open transaction, this method does nothing. If `autocommit` is `False`, a new transaction is implicitly opened if a pending transaction was committed by this method.

rollback()

Roll back to the start of any pending transaction. If *autocommit* is `True`, or there is no open transaction, this method does nothing. If `autocommit` is `False`, a new transaction is implicitly opened if a pending transaction was rolled back by this method.

close()

Close the database connection. If *autocommit* is `False`, any pending transaction is implicitly rolled back. If `autocommit` is `True` or *LEGACY_TRANSACTION_CONTROL*, no implicit transaction control is executed. Make sure to *commit()* before closing to avoid losing pending changes.

execute(*sql*, *parameters=()*, */*)

Create a new *Cursor* object and call *execute()* on it with the given *sql* and *parameters*. Return the new cursor object.

executemany(*sql*, *parameters*, */*)

Create a new *Cursor* object and call *executemany()* on it with the given *sql* and *parameters*. Return the new cursor object.

executescript(*sql_script*, */*)

Create a new *Cursor* object and call *executescript()* on it with the given *sql_script*. Return the new cursor object.

create_function(*name*, *narg*, *func*, ***, *deterministic=False*)

Create or remove a user-defined SQL function.

Parameters

- **name** (str) – The name of the SQL function.
- **narg** (int) – The number of arguments the SQL function can accept. If `-1`, it may take any number of arguments.

- **func** (*callback* | None) – A *callable* that is called when the SQL function is invoked. The callable must return *a type natively supported by SQLite*. Set to `None` to remove an existing SQL function.
- **deterministic** (`bool`) – If `True`, the created SQL function is marked as deterministic, which allows SQLite to perform additional optimizations.

Changed in version 3.8: Added the *deterministic* parameter.

Example:

```
>>> import hashlib
>>> def md5sum(t):
...     return hashlib.md5(t).hexdigest()
>>> con = sqlite3.connect(":memory:")
>>> con.create_function("md5", 1, md5sum)
>>> for row in con.execute("SELECT md5(?)", (b"foo",)):
...     print(row)
('acbd18db4cc2f85cedef654fccc4a4d8',)
>>> con.close()
```

Changed in version 3.13: Passing *name*, *narg*, and *func* as keyword arguments is deprecated. These parameters will become positional-only in Python 3.15.

create_aggregate(*name*, *n_arg*, *aggregate_class*)

Create or remove a user-defined SQL aggregate function.

Parameters

- **name** (`str`) – The name of the SQL aggregate function.
- **n_arg** (`int`) – The number of arguments the SQL aggregate function can accept. If `-1`, it may take any number of arguments.
- **aggregate_class** (*class* | None) – A class must implement the following methods:
  - `step()`: Add a row to the aggregate.
  - `finalize()`: Return the final result of the aggregate as *a type natively supported by SQLite*.

  The number of arguments that the `step()` method must accept is controlled by *n_arg*.

  Set to `None` to remove an existing SQL aggregate function.

Example:

```
class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.execute("CREATE TABLE test(i)")
cur.execute("INSERT INTO test(i) VALUES(1)")
cur.execute("INSERT INTO test(i) VALUES(2)")
cur.execute("SELECT mysum(i) FROM test")
print(cur.fetchone()[0])
```

(continues on next page)

(continued from previous page)

```
con.close()
```

Changed in version 3.13: Passing *name*, *n_arg*, and *aggregate_class* as keyword arguments is deprecated. These parameters will become positional-only in Python 3.15.

create_window_function(*name*, *num_params*, *aggregate_class*, */*)

Create or remove a user-defined aggregate window function.

Parameters

- **name** (str) – The name of the SQL aggregate window function to create or remove.
- **num_params** (int) – The number of arguments the SQL aggregate window function can accept. If `-1`, it may take any number of arguments.
- **aggregate_class** (*class* | None) – A class that must implement the following methods:
  - `step()`: Add a row to the current window.
  - `value()`: Return the current value of the aggregate.
  - `inverse()`: Remove a row from the current window.
  - `finalize()`: Return the final result of the aggregate as *a type natively supported by SQLite*.

  The number of arguments that the `step()` and `value()` methods must accept is controlled by *num_params*.

  Set to `None` to remove an existing SQL aggregate window function.

Raises

NotSupportedError – If used with a version of SQLite older than 3.25.0, which does not support aggregate window functions.

Added in version 3.11.

Example:

```
# Example taken from https://www.sqlite.org/windowfunctions.html#udfwinfunc
class WindowSumInt:
    def __init__(self):
        self.count = 0

    def step(self, value):
        """Add a row to the current window."""
        self.count += value

    def value(self):
        """Return the current value of the aggregate."""
        return self.count

    def inverse(self, value):
        """Remove a row from the current window."""
        self.count -= value

    def finalize(self):
        """Return the final value of the aggregate.

        Any clean-up actions should be placed here.
        """
        return self.count
```

(continues on next page)

(continued from previous page)

```
con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE test(x, y)")
values = [
    ("a", 4),
    ("b", 5),
    ("c", 3),
    ("d", 8),
    ("e", 1),
]
cur.executemany("INSERT INTO test VALUES(?, ?)", values)
con.create_window_function("sumint", 1, WindowSumInt)
cur.execute("""
    SELECT x, sumint(y) OVER (
        ORDER BY x ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING
    ) AS sum_y
    FROM test ORDER BY x
""")
print(cur.fetchall())
con.close()
```

create_collation(*name*, *callable*, */*)

Create a collation named *name* using the collating function *callable*. *callable* is passed two *string* arguments, and it should return an *integer*:

- `1` if the first is ordered higher than the second
- `-1` if the first is ordered lower than the second
- `0` if they are ordered equal

The following example shows a reverse sorting collation:

```
def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.execute("CREATE TABLE test(x)")
cur.executemany("INSERT INTO test(x) VALUES(?)", [("a",), ("b",)])
cur.execute("SELECT x FROM test ORDER BY x COLLATE reverse")
for row in cur:
    print(row)
con.close()
```

Remove a collation function by setting *callable* to `None`.

Changed in version 3.11: The collation name can contain any Unicode character. Earlier, only ASCII characters were allowed.

interrupt()

Call this method from a different thread to abort any queries that might be executing on the connection. Aborted queries will raise an *OperationalError*.

set_authorizer(*authorizer_callback*)

Register *callable* *authorizer_callback* to be invoked for each attempt to access a column of a table in the database. The callback should return one of *SQLITE_OK*, *SQLITE_DENY*, or *SQLITE_IGNORE* to signal how access to the column should be handled by the underlying SQLite library.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database ("main", "temp", etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the `sqlite3` module.

Passing `None` as *authorizer_callback* will disable the authorizer.

Changed in version 3.11: Added support for disabling the authorizer using `None`.

Changed in version 3.13: Passing *authorizer_callback* as a keyword argument is deprecated. The parameter will become positional-only in Python 3.15.

set_progress_handler(*progress_handler*, *n*)

Register *callable* *progress_handler* to be invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with `None` for *progress_handler*.

Returning a non-zero value from the handler function will terminate the currently executing query and cause it to raise a *DatabaseError* exception.

Changed in version 3.13: Passing *progress_handler* as a keyword argument is deprecated. The parameter will become positional-only in Python 3.15.

set_trace_callback(*trace_callback*)

Register *callable* *trace_callback* to be invoked for each SQL statement that is actually executed by the SQLite backend.

The only argument passed to the callback is the statement (as *str*) that is being executed. The return value of the callback is ignored. Note that the backend does not only run statements passed to the *Cursor.execute()* methods. Other sources include the *transaction management* of the `sqlite3` module and the execution of triggers defined in the current database.

Passing `None` as *trace_callback* will disable the trace callback.

> **Note**
>
> Exceptions raised in the trace callback are not propagated. As a development and debugging aid, use *enable_callback_tracebacks()* to enable printing tracebacks from exceptions raised in the trace callback.

Added in version 3.3.

Changed in version 3.13: Passing *trace_callback* as a keyword argument is deprecated. The parameter will become positional-only in Python 3.15.

enable_load_extension(*enabled*, /)

Enable the SQLite engine to load SQLite extensions from shared libraries if *enabled* is `True`; else, disallow loading SQLite extensions. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

> **Note**
>
> The `sqlite3` module is not built with loadable extension support by default, because some platforms (notably macOS) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must pass the `--enable-loadable-sqlite-extensions` option to **`configure`**.

Raises an *auditing event* `sqlite3.enable_load_extension` with arguments `connection`, `enabled`.

Added in version 3.2.

Changed in version 3.10: Added the `sqlite3.enable_load_extension` auditing event.

```
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("CREATE VIRTUAL TABLE recipe USING fts3(name, ingredients)")
con.executescript("""
    INSERT INTO recipe (name, ingredients) VALUES('broccoli stew',
↪'broccoli peppers cheese tomatoes');
    INSERT INTO recipe (name, ingredients) VALUES('pumpkin stew', 'pumpkin␣
↪onions garlic celery');
    INSERT INTO recipe (name, ingredients) VALUES('broccoli pie',
↪'broccoli cheese onions flour');
    INSERT INTO recipe (name, ingredients) VALUES('pumpkin pie', 'pumpkin␣
↪sugar flour butter');
    """)
for row in con.execute("SELECT rowid, name, ingredients FROM recipe WHERE␣
↪name MATCH 'pie'"):
    print(row)
```

`load_extension`(*path*, */*, ***, *entrypoint=None*)

Load an SQLite extension from a shared library. Enable extension loading with *`enable_load_extension()`* before calling this method.

Parameters

- **`path`** (`str`) – The path to the SQLite extension.
- **`entrypoint`** (`str` | *None*) – Entry point name. If `None` (the default), SQLite will come up with an entry point name of its own; see the SQLite docs Loading an Extension for details.

Raises an *auditing event* `sqlite3.load_extension` with arguments `connection`, `path`.

Added in version 3.2.

Changed in version 3.10: Added the `sqlite3.load_extension` auditing event.

Changed in version 3.12: Added the *entrypoint* parameter.

iterdump(*, *filter=None*)

Return an *iterator* to dump the database as SQL source code. Useful when saving an in-memory database for later restoration. Similar to the `.dump` command in the **sqlite3** shell.

Parameters

filter (`str` | *None*) – An optional `LIKE` pattern for database objects to dump, e.g. `prefix_%`. If `None` (the default), all database objects will be included.

Example:

```
# Convert file example.db to SQL dump file dump.sql
con = sqlite3.connect('example.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
con.close()
```

See also

How to handle non-UTF-8 text encodings

Changed in version 3.13: Added the *filter* parameter.

backup(*target*, *, *pages=-1*, *progress=None*, *name='main'*, *sleep=0.250*)

Create a backup of an SQLite database.

Works even if the database is being accessed by other clients or concurrently by the same connection.

Parameters

- **target** (`Connection`) – The database connection to save the backup to.
- **pages** (`int`) – The number of pages to copy at a time. If equal to or less than `0`, the entire database is copied in a single step. Defaults to `-1`.
- **progress** (*callback* | None) – If set to a *callable*, it is invoked with three integer arguments for every backup iteration: the *status* of the last iteration, the *remaining* number of pages still to be copied, and the *total* number of pages. Defaults to `None`.
- **name** (`str`) – The name of the database to back up. Either `"main"` (the default) for the main database, `"temp"` for the temporary database, or the name of a custom database as attached using the `ATTACH DATABASE` SQL statement.
- **sleep** (`float`) – The number of seconds to sleep between successive attempts to back up remaining pages.

Example 1, copy an existing database into another:

```
def progress(status, remaining, total):
    print(f'Copied {total-remaining} of {total} pages...')

src = sqlite3.connect('example.db')
dst = sqlite3.connect('backup.db')
with dst:
    src.backup(dst, pages=1, progress=progress)
dst.close()
src.close()
```

Example 2, copy an existing database into a transient copy:

```
src = sqlite3.connect('example.db')
dst = sqlite3.connect(':memory:')
src.backup(dst)
dst.close()
src.close()
```

Added in version 3.7.

See also

How to handle non-UTF-8 text encodings

getlimit(*category*, */*)

Get a connection runtime limit.

Parameters

category (int) – The SQLite limit category to be queried.

Return type

int

Raises

ProgrammingError – If *category* is not recognised by the underlying SQLite library.

Example, query the maximum length of an SQL statement for *Connection* `con` (the default is 1000000000):

```
>>> con.getlimit(sqlite3.SQLITE_LIMIT_SQL_LENGTH)
1000000000
```

Added in version 3.11.

setlimit(*category*, *limit*, */*)

Set a connection runtime limit. Attempts to increase a limit above its hard upper bound are silently truncated to the hard upper bound. Regardless of whether or not the limit was changed, the prior value of the limit is returned.

Parameters

- **category** (int) – The SQLite limit category to be set.
- **limit** (int) – The value of the new limit. If negative, the current limit is unchanged.

Return type

int

Raises

ProgrammingError – If *category* is not recognised by the underlying SQLite library.

Example, limit the number of attached databases to 1 for *Connection* `con` (the default limit is 10):

```
>>> con.setlimit(sqlite3.SQLITE_LIMIT_ATTACHED, 1)
10
>>> con.getlimit(sqlite3.SQLITE_LIMIT_ATTACHED)
1
```

Added in version 3.11.

getconfig(*op*, */*)

Query a boolean connection configuration option.

Parameters

op (int) – A *SQLITE_DBCONFIG code*.

Return type
bool

Added in version 3.12.

setconfig(*op*, *enable=True*, */*)

Set a boolean connection configuration option.

Parameters

- **op** (`int`) – A *SQLITE_DBCONFIG code*.
- **enable** (`bool`) – `True` if the configuration option should be enabled (default); `False` if it should be disabled.

Added in version 3.12.

serialize(***, *name='main'*)

Serialize a database into a *bytes* object. For an ordinary on-disk database file, the serialization is just a copy of the disk file. For an in-memory database or a "temp" database, the serialization is the same sequence of bytes which would be written to disk if that database were backed up to disk.

Parameters
name (`str`) – The database name to be serialized. Defaults to `"main"`.

Return type
bytes

> **Note**
> This method is only available if the underlying SQLite library has the serialize API.

Added in version 3.11.

deserialize(*data*, */*, ***, *name='main'*)

Deserialize a *serialized* database into a *Connection*. This method causes the database connection to disconnect from database *name*, and reopen *name* as an in-memory database based on the serialization contained in *data*.

Parameters

- **data** (`bytes`) – A serialized database.
- **name** (`str`) – The database name to deserialize into. Defaults to `"main"`.

Raises

- ***OperationalError*** – If the database connection is currently involved in a read transaction or a backup operation.
- ***DatabaseError*** – If *data* does not contain a valid SQLite database.
- ***OverflowError*** – If *len(data)* is larger than `2**63 - 1`.

> **Note**
> This method is only available if the underlying SQLite library has the deserialize API.

Added in version 3.11.

autocommit

This attribute controls **PEP 249**-compliant transaction behaviour. `autocommit` has three allowed values:

- `False`: Select **PEP 249**-compliant transaction behaviour, implying that `sqlite3` ensures a transaction is always open. Use *`commit()`* and *`rollback()`* to close transactions.

  This is the recommended value of `autocommit`.

- `True`: Use SQLite's autocommit mode. *`commit()`* and *`rollback()`* have no effect in this mode.

- *`LEGACY_TRANSACTION_CONTROL`*: Pre-Python 3.12 (non-**PEP 249**-compliant) transaction control. See *`isolation_level`* for more details.

  This is currently the default value of `autocommit`.

Changing `autocommit` to `False` will open a new transaction, and changing it to `True` will commit any pending transaction.

See *Transaction control via the autocommit attribute* for more details.

> **Note**
>
> The *`isolation_level`* attribute has no effect unless *`autocommit`* is *`LEGACY_TRANSACTION_CONTROL`*.

Added in version 3.12.

`in_transaction`

This read-only attribute corresponds to the low-level SQLite autocommit mode.

`True` if a transaction is active (there are uncommitted changes), `False` otherwise.

Added in version 3.2.

`isolation_level`

Controls the *legacy transaction handling mode* of `sqlite3`. If set to `None`, transactions are never implicitly opened. If set to one of `"DEFERRED"`, `"IMMEDIATE"`, or `"EXCLUSIVE"`, corresponding to the underlying SQLite transaction behaviour, *implicit transaction management* is performed.

If not overridden by the *isolation_level* parameter of *`connect()`*, the default is `""`, which is an alias for `"DEFERRED"`.

> **Note**
>
> Using *`autocommit`* to control transaction handling is recommended over using `isolation_level`. `isolation_level` has no effect unless *`autocommit`* is set to *`LEGACY_TRANSACTION_CONTROL`* (the default).

`row_factory`

The initial *`row_factory`* for *`Cursor`* objects created from this connection. Assigning to this attribute does not affect the `row_factory` of existing cursors belonging to this connection, only new ones. Is `None` by default, meaning each row is returned as a *`tuple`*.

See *How to create and use row factories* for more details.

`text_factory`

A *callable* that accepts a *`bytes`* parameter and returns a text representation of it. The callable is invoked for SQLite values with the `TEXT` data type. By default, this attribute is set to *`str`*.

See *How to handle non-UTF-8 text encodings* for more details.

`total_changes`

Return the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.

Cursor objects

A `Cursor` object represents a database cursor which is used to execute SQL statements, and manage the context of a fetch operation. Cursors are created using *`Connection.cursor()`*, or by using any of the *connection shortcut methods*.

Cursor objects are *iterators*, meaning that if you *`execute()`* a `SELECT` query, you can simply iterate over the cursor to fetch the resulting rows:

```
for row in cur.execute("SELECT t FROM data"):
    print(row)
```

class sqlite3.**Cursor**

A *`Cursor`* instance has the following attributes and methods.

execute(*sql*, *parameters=()*, */*)

Execute a single SQL statement, optionally binding Python values using *placeholders*.

Parameters

- **sql** (`str`) – A single SQL statement.
- **parameters** (*`dict`* | *sequence*) – Python values to bind to placeholders in *sql*. A `dict` if named placeholders are used. A sequence if unnamed placeholders are used. See *How to use placeholders to bind values in SQL queries*.

Raises

`ProgrammingError` – If *sql* contains more than one SQL statement.

If *`autocommit`* is *`LEGACY_TRANSACTION_CONTROL`*, *`isolation_level`* is not `None`, *sql* is an `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statement, and there is no open transaction, a transaction is implicitly opened before executing *sql*.

Deprecated since version 3.12, will be removed in version 3.14: *`DeprecationWarning`* is emitted if *named placeholders* are used and *parameters* is a sequence instead of a *`dict`*. Starting with Python 3.14, *`ProgrammingError`* will be raised instead.

Use *`executescript()`* to execute multiple SQL statements.

executemany(*sql*, *parameters*, */*)

For every item in *parameters*, repeatedly execute the *parameterized* DML (Data Manipulation Language) SQL statement *sql*.

Uses the same implicit transaction handling as *`execute()`*.

Parameters

- **sql** (`str`) – A single SQL DML statement.
- **parameters** (*iterable*) – An iterable of parameters to bind with the placeholders in *sql*. See *How to use placeholders to bind values in SQL queries*.

Raises

`ProgrammingError` – If *sql* contains more than one SQL statement, or is not a DML statement.

Example:

```
rows = [
    ("row1",),
    ("row2",),
]
# cur is an sqlite3.Cursor object
cur.executemany("INSERT INTO data VALUES(?)", rows)
```

> **Note**
>
> Any resulting rows are discarded, including DML statements with RETURNING clauses.

Deprecated since version 3.12, will be removed in version 3.14: *DeprecationWarning* is emitted if *named placeholders* are used and the items in *parameters* are sequences instead of *dict*s. Starting with Python 3.14, *ProgrammingError* will be raised instead.

executescript(*sql_script*, /)

Execute the SQL statements in *sql_script*. If the *autocommit* is *LEGACY_TRANSACTION_CONTROL* and there is a pending transaction, an implicit COMMIT statement is executed first. No other implicit transaction control is performed; any transaction control must be added to *sql_script*.

sql_script must be a *string*.

Example:

```
# cur is an sqlite3.Cursor object
cur.executescript("""
    BEGIN;
    CREATE TABLE person(firstname, lastname, age);
    CREATE TABLE book(title, author, published);
    CREATE TABLE publisher(name, address);
    COMMIT;
""")
```

fetchone()

If *row_factory* is None, return the next row query result set as a *tuple*. Else, pass it to the row factory and return its result. Return None if no more data is available.

fetchmany(*size=cursor.arraysize*)

Return the next set of rows of a query result as a *list*. Return an empty list if no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If *size* is not given, *arraysize* determines the number of rows to be fetched. If fewer than *size* rows are available, as many rows as are available are returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the arraysize attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

fetchall()

Return all (remaining) rows of a query result as a *list*. Return an empty list if no rows are available. Note that the *arraysize* attribute can affect the performance of this operation.

close()

Close the cursor now (rather than whenever __del__ is called).

The cursor will be unusable from this point forward; a *ProgrammingError* exception will be raised if any operation is attempted with the cursor.

setinputsizes(*sizes*, /)

Required by the DB-API. Does nothing in sqlite3.

setoutputsize(*size*, *column=None*, /)

Required by the DB-API. Does nothing in sqlite3.

arraysize

Read/write attribute that controls the number of rows returned by *fetchmany()*. The default value is 1 which means a single row would be fetched per call.

connection

Read-only attribute that provides the SQLite database *Connection* belonging to the cursor. A *Cursor* object created by calling *con.cursor()* will have a *connection* attribute that refers to *con*:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
>>> con.close()
```

description

Read-only attribute that provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are `None`.

It is set for `SELECT` statements without any matching rows as well.

lastrowid

Read-only attribute that provides the row id of the last inserted row. It is only updated after successful `INSERT` or `REPLACE` statements using the *execute()* method. For other statements, after *executemany()* or *executescript()*, or if the insertion failed, the value of `lastrowid` is left unchanged. The initial value of `lastrowid` is `None`.

> **Note**
>
> Inserts into `WITHOUT ROWID` tables are not recorded.

Changed in version 3.6: Added support for the `REPLACE` statement.

rowcount

Read-only attribute that provides the number of modified rows for `INSERT`, `UPDATE`, `DELETE`, and `REPLACE` statements; is `-1` for other statements, including CTE (Common Table Expression) queries. It is only updated by the *execute()* and *executemany()* methods, after the statement has run to completion. This means that any resulting rows must be fetched in order for `rowcount` to be updated.

row_factory

Control how a row fetched from this `Cursor` is represented. If `None`, a row is represented as a *tuple*. Can be set to the included *sqlite3.Row*; or a *callable* that accepts two arguments, a *Cursor* object and the `tuple` of row values, and returns a custom object representing an SQLite row.

Defaults to what *Connection.row_factory* was set to when the `Cursor` was created. Assigning to this attribute does not affect *Connection.row_factory* of the parent connection.

See *How to create and use row factories* for more details.

Row objects

class sqlite3.**Row**

A `Row` instance serves as a highly optimized *row_factory* for *Connection* objects. It supports iteration, equality testing, *len()*, and *mapping* access by column name and index.

Two `Row` objects compare equal if they have identical column names and values.

See *How to create and use row factories* for more details.

keys()

Return a *list* of column names as *strings*. Immediately after a query, it is the first member of each tuple in *Cursor.description*.

Changed in version 3.5: Added support of slicing.

Blob objects

class sqlite3.**Blob**

Added in version 3.11.

A *Blob* instance is a *file-like object* that can read and write data in an SQLite BLOB. Call *len(blob)* to get the size (number of bytes) of the blob. Use indices and *slices* for direct access to the blob data.

Use the *Blob* as a *context manager* to ensure that the blob handle is closed after use.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE test(blob_col blob)")
con.execute("INSERT INTO test(blob_col) VALUES(zeroblob(13))")

# Write to our blob, using two write operations:
with con.blobopen("test", "blob_col", 1) as blob:
    blob.write(b"hello, ")
    blob.write(b"world.")
    # Modify the first and last bytes of our blob
    blob[0] = ord("H")
    blob[-1] = ord("!")

# Read the contents of our blob
with con.blobopen("test", "blob_col", 1) as blob:
    greeting = blob.read()

print(greeting)  # outputs "b'Hello, world!'"
con.close()
```

close()

Close the blob.

The blob will be unusable from this point onward. An *Error* (or subclass) exception will be raised if any further operation is attempted with the blob.

read(*length=-1*, */*)

Read *length* bytes of data from the blob at the current offset position. If the end of the blob is reached, the data up to EOF (End of File) will be returned. When *length* is not specified, or is negative, *read()* will read until the end of the blob.

write(*data*, */*)

Write *data* to the blob at the current offset. This function cannot change the blob length. Writing beyond the end of the blob will raise *ValueError*.

tell()

Return the current access position of the blob.

seek(*offset*, *origin=os.SEEK_SET*, */*)

Set the current access position of the blob to *offset*. The *origin* argument defaults to *os.SEEK_SET* (absolute blob positioning). Other values for *origin* are *os.SEEK_CUR* (seek relative to the current position) and *os.SEEK_END* (seek relative to the blob's end).

PrepareProtocol objects

class sqlite3.**PrepareProtocol**

The PrepareProtocol type's single purpose is to act as a **PEP 246** style adaption protocol for objects that can *adapt themselves* to *native SQLite types*.

Exceptions

The exception hierarchy is defined by the DB-API 2.0 (**PEP 249**).

exception sqlite3.**Warning**

This exception is not currently raised by the `sqlite3` module, but may be raised by applications using `sqlite3`, for example if a user-defined function truncates data while inserting. `Warning` is a subclass of *`Exception`*.

exception sqlite3.**Error**

The base class of the other exceptions in this module. Use this to catch all errors with one single `except` statement. `Error` is a subclass of *`Exception`*.

If the exception originated from within the SQLite library, the following two attributes are added to the exception:

sqlite_errorcode

The numeric error code from the SQLite API

Added in version 3.11.

sqlite_errorname

The symbolic name of the numeric error code from the SQLite API

Added in version 3.11.

exception sqlite3.**InterfaceError**

Exception raised for misuse of the low-level SQLite C API. In other words, if this exception is raised, it probably indicates a bug in the `sqlite3` module. `InterfaceError` is a subclass of *`Error`*.

exception sqlite3.**DatabaseError**

Exception raised for errors that are related to the database. This serves as the base exception for several types of database errors. It is only raised implicitly through the specialised subclasses. `DatabaseError` is a subclass of *`Error`*.

exception sqlite3.**DataError**

Exception raised for errors caused by problems with the processed data, like numeric values out of range, and strings which are too long. `DataError` is a subclass of *`DatabaseError`*.

exception sqlite3.**OperationalError**

Exception raised for errors that are related to the database's operation, and not necessarily under the control of the programmer. For example, the database path is not found, or a transaction could not be processed. `OperationalError` is a subclass of *`DatabaseError`*.

exception sqlite3.**IntegrityError**

Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of *`DatabaseError`*.

exception sqlite3.**InternalError**

Exception raised when SQLite encounters an internal error. If this is raised, it may indicate that there is a problem with the runtime SQLite library. `InternalError` is a subclass of *`DatabaseError`*.

exception sqlite3.**ProgrammingError**

Exception raised for `sqlite3` API programming errors, for example supplying the wrong number of bindings to a query, or trying to operate on a closed *`Connection`*. `ProgrammingError` is a subclass of *`DatabaseError`*.

exception sqlite3.**NotSupportedError**

Exception raised in case a method or database API is not supported by the underlying SQLite library. For example, setting *deterministic* to `True` in *`create_function()`*, if the underlying SQLite library does not support deterministic functions. `NotSupportedError` is a subclass of *`DatabaseError`*.

SQLite and Python types

SQLite natively supports the following types: `NULL`, `INTEGER`, `REAL`, `TEXT`, `BLOB`.

The following Python types can thus be sent to SQLite without any problem:

Python type	SQLite type
`None`	`NULL`
`int`	`INTEGER`
`float`	`REAL`
`str`	`TEXT`
`bytes`	`BLOB`

This is how SQLite types are converted to Python types by default:

SQLite type	Python type
`NULL`	`None`
`INTEGER`	*`int`*
`REAL`	*`float`*
`TEXT`	depends on *`text_factory`*, *`str`* by default
`BLOB`	*`bytes`*

The type system of the `sqlite3` module is extensible in two ways: you can store additional Python types in an SQLite database via *object adapters*, and you can let the `sqlite3` module convert SQLite types to Python types via *converters*.

Default adapters and converters (deprecated)

Note

The default adapters and converters are deprecated as of Python 3.12. Instead, use the *Adapter and converter recipes* and tailor them to your needs.

The deprecated default adapters and converters consist of:

- An adapter for *`datetime.date`* objects to *`strings`* in ISO 8601 format.
- An adapter for *`datetime.datetime`* objects to strings in ISO 8601 format.
- A converter for *declared* "date" types to *`datetime.date`* objects.
- A converter for declared "timestamp" types to *`datetime.datetime`* objects. Fractional parts will be truncated to 6 digits (microsecond precision).

Note

The default "timestamp" converter ignores UTC offsets in the database and always returns a naive *`datetime.datetime`* object. To preserve UTC offsets in timestamps, either leave converters disabled, or register an offset-aware converter with *`register_converter()`*.

Deprecated since version 3.12.

Command-line interface

The `sqlite3` module can be invoked as a script, using the interpreter's `-m` switch, in order to provide a simple SQLite shell. The argument signature is as follows:

```
python -m sqlite3 [-h] [-v] [filename] [sql]
```

Type `.quit` or CTRL-D to exit the shell.

`-h, --help`
Print CLI help.

`-v, --version`
Print underlying SQLite library version.

Added in version 3.12.

12.6.3 How-to guides

How to use placeholders to bind values in SQL queries

SQL operations usually need to use values from Python variables. However, beware of using Python's string operations to assemble queries, as they are vulnerable to SQL injection attacks. For example, an attacker can simply close the single quote and inject `OR TRUE` to select all rows:

```
>>> # Never do this -- insecure!
>>> symbol = input()
' OR TRUE; --
>>> sql = "SELECT * FROM stocks WHERE symbol = '%s'" % symbol
>>> print(sql)
SELECT * FROM stocks WHERE symbol = '' OR TRUE; --'
>>> cur.execute(sql)
```

Instead, use the DB-API's parameter substitution. To insert a variable into a query string, use a placeholder in the string, and substitute the actual values into the query by providing them as a *`tuple`* of values to the second argument of the cursor's *`execute()`* method.

An SQL statement may use one of two kinds of placeholders: question marks (qmark style) or named placeholders (named style). For the qmark style, *parameters* must be a *sequence* whose length must match the number of placeholders, or a *`ProgrammingError`* is raised. For the named style, *parameters* must be an instance of a *`dict`* (or a subclass), which must contain keys for all named parameters; any extra items are ignored. Here's an example of both styles:

```
con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE lang(name, first_appeared)")

# This is the named style used with executemany():
data = (
    {"name": "C", "year": 1972},
    {"name": "Fortran", "year": 1957},
    {"name": "Python", "year": 1991},
    {"name": "Go", "year": 2009},
)
cur.executemany("INSERT INTO lang VALUES(:name, :year)", data)

# This is the qmark style used in a SELECT query:
params = (1972,)
cur.execute("SELECT * FROM lang WHERE first_appeared = ?", params)
print(cur.fetchall())
con.close()
```

Note

PEP 249 numeric placeholders are *not* supported. If used, they will be interpreted as named placeholders.

How to adapt custom Python types to SQLite values

SQLite supports only a limited set of data types natively. To store custom Python types in SQLite databases, *adapt* them to one of the *Python types SQLite natively understands*.

There are two ways to adapt Python objects to SQLite types: letting your object adapt itself, or using an *adapter callable*. The latter will take precedence above the former. For a library that exports a custom type, it may make sense to enable that type to adapt itself. As an application developer, it may make more sense to take direct control by registering custom adapter functions.

How to write adaptable objects

Suppose we have a `Point` class that represents a pair of coordinates, `x` and `y`, in a Cartesian coordinate system. The coordinate pair will be stored as a text string in the database, using a semicolon to separate the coordinates. This can be implemented by adding a `__conform__(self, protocol)` method which returns the adapted value. The object passed to *protocol* will be of type *`PrepareProtocol`*.

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return f"{self.x};{self.y}"

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(4.0, -3.2),))
print(cur.fetchone()[0])
con.close()
```

How to register adapter callables

The other possibility is to create a function that converts the Python object to an SQLite-compatible type. This function can then be registered using *`register_adapter()`*.

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return f"{point.x};{point.y}"

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(1.0, 2.5),))
print(cur.fetchone()[0])
con.close()
```

How to convert SQLite values to custom Python types

Writing an adapter lets you convert *from* custom Python types *to* SQLite values. To be able to convert *from* SQLite values *to* custom Python types, we use *converters*.

Let's go back to the `Point` class. We stored the x and y coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

> **Note**
>
> Converter functions are **always** passed a *bytes* object, no matter the underlying SQLite data type.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

We now need to tell `sqlite3` when it should convert a given SQLite value. This is done when connecting to a database, using the *detect_types* parameter of *connect()*. There are three options:

- Implicit: set *detect_types* to *PARSE_DECLTYPES*
- Explicit: set *detect_types* to *PARSE_COLNAMES*
- Both: set *detect_types* to `sqlite3.PARSE_DECLTYPES | sqlite3.PARSE_COLNAMES`. Column names take precedence over declared types.

The following example illustrates the implicit and explicit approaches:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return f"Point({self.x}, {self.y})"

def adapt_point(point):
    return f"{point.x};{point.y}"

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
    return Point(x, y)

# Register the adapter and converter
sqlite3.register_adapter(Point, adapt_point)
sqlite3.register_converter("point", convert_point)

# 1) Parse using declared types
p = Point(4.0, -3.2)
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.execute("CREATE TABLE test(p point)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute("SELECT p FROM test")
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()

# 2) Parse using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
```

(continues on next page)

(continued from previous page)

```
cur = con.execute("CREATE TABLE test(p)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute('SELECT p AS "p [point]" FROM test')
print("with column names:", cur.fetchone()[0])
cur.close()
con.close()
```

Adapter and converter recipes

This section shows recipes for common adapters and converters.

```
import datetime
import sqlite3

def adapt_date_iso(val):
    """Adapt datetime.date to ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_iso(val):
    """Adapt datetime.datetime to timezone-naive ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_epoch(val):
    """Adapt datetime.datetime to Unix timestamp."""
    return int(val.timestamp())

sqlite3.register_adapter(datetime.date, adapt_date_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_epoch)

def convert_date(val):
    """Convert ISO 8601 date to datetime.date object."""
    return datetime.date.fromisoformat(val.decode())

def convert_datetime(val):
    """Convert ISO 8601 datetime to datetime.datetime object."""
    return datetime.datetime.fromisoformat(val.decode())

def convert_timestamp(val):
    """Convert Unix epoch timestamp to datetime.datetime object."""
    return datetime.datetime.fromtimestamp(int(val))

sqlite3.register_converter("date", convert_date)
sqlite3.register_converter("datetime", convert_datetime)
sqlite3.register_converter("timestamp", convert_timestamp)
```

How to use connection shortcut methods

Using the *execute()*, *executemany()*, and *executescript()* methods of the *Connection* class, your code can be written more concisely because you don't have to create the (often superfluous) *Cursor* objects explicitly. Instead, the *Cursor* objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a SELECT statement and iterate over it directly using only a single call on the *Connection* object.

```
# Create and fill the table.
con = sqlite3.connect(":memory:")
```

(continues on next page)

(continued from previous page)

```
con.execute("CREATE TABLE lang(name, first_appeared)")
data = [
    ("C++", 1985),
    ("Objective-C", 1984),
]
con.executemany("INSERT INTO lang(name, first_appeared) VALUES(?, ?)", data)

# Print the table contents
for row in con.execute("SELECT name, first_appeared FROM lang"):
    print(row)

print("I just deleted", con.execute("DELETE FROM lang").rowcount, "rows")

# close() is not a shortcut method and it's not called automatically;
# the connection object should be closed manually
con.close()
```

How to use the connection context manager

A *Connection* object can be used as a context manager that automatically commits or rolls back open transactions when leaving the body of the context manager. If the body of the `with` statement finishes without exceptions, the transaction is committed. If this commit fails, or if the body of the `with` statement raises an uncaught exception, the transaction is rolled back. If *autocommit* is `False`, a new transaction is implicitly opened after committing or rolling back.

If there is no open transaction upon leaving the body of the `with` statement, or if *autocommit* is `True`, the context manager does nothing.

> **Note**
>
> The context manager neither implicitly opens a new transaction nor closes the connection. If you need a closing context manager, consider using *contextlib.closing()*.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(id INTEGER PRIMARY KEY, name VARCHAR UNIQUE)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("INSERT INTO lang(name) VALUES(?)", ("Python",))

# con.rollback() is called after the with block finishes with an exception,
# the exception is still raised and must be caught
try:
    with con:
        con.execute("INSERT INTO lang(name) VALUES(?)", ("Python",))
except sqlite3.IntegrityError:
    print("couldn't add Python twice")

# Connection object used as context manager only commits or rollbacks transactions,
# so the connection object should be closed manually
con.close()
```

How to work with SQLite URIs

Some useful URI tricks include:

- Open a database in read-only mode:

```
>>> con = sqlite3.connect("file:tutorial.db?mode=ro", uri=True)
>>> con.execute("CREATE TABLE readonly(data)")
Traceback (most recent call last):
OperationalError: attempt to write a readonly database
>>> con.close()
```

- Do not implicitly create a new database file if it does not already exist; will raise *OperationalError* if unable to create a new file:

```
>>> con = sqlite3.connect("file:nosuchdb.db?mode=rw", uri=True)
Traceback (most recent call last):
OperationalError: unable to open database file
```

- Create a shared named in-memory database:

```
db = "file:mem1?mode=memory&cache=shared"
con1 = sqlite3.connect(db, uri=True)
con2 = sqlite3.connect(db, uri=True)
with con1:
    con1.execute("CREATE TABLE shared(data)")
    con1.execute("INSERT INTO shared VALUES(28)")
res = con2.execute("SELECT data FROM shared")
assert res.fetchone() == (28,)

con1.close()
con2.close()
```

More information about this feature, including a list of parameters, can be found in the SQLite URI documentation.

How to create and use row factories

By default, `sqlite3` represents each row as a *tuple*. If a `tuple` does not suit your needs, you can use the *sqlite3.Row* class or a custom *row_factory*.

While `row_factory` exists as an attribute both on the *Cursor* and the *Connection*, it is recommended to set *Connection.row_factory*, so all cursors created from the connection will use the same row factory.

`Row` provides indexed and case-insensitive named access to columns, with minimal memory overhead and performance impact over a `tuple`. To use `Row` as a row factory, assign it to the `row_factory` attribute:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = sqlite3.Row
```

Queries now return `Row` objects:

```
>>> res = con.execute("SELECT 'Earth' AS name, 6378 AS radius")
>>> row = res.fetchone()
>>> row.keys()
['name', 'radius']
>>> row[0]          # Access by index.
'Earth'
>>> row["name"]     # Access by name.
'Earth'
>>> row["RADIUS"]   # Column names are case-insensitive.
```

(continues on next page)

(continued from previous page)

```
6378
>>> con.close()
```

Note

The `FROM` clause can be omitted in the `SELECT` statement, as in the above example. In such cases, SQLite returns a single row with columns defined by expressions, e.g. literals, with the given aliases `expr AS alias`.

You can create a custom *row_factory* that returns each row as a *dict*, with column names mapped to values:

```
def dict_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    return {key: value for key, value in zip(fields, row)}
```

Using it, queries now return a `dict` instead of a `tuple`:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = dict_factory
>>> for row in con.execute("SELECT 1 AS a, 2 AS b"):
...     print(row)
{'a': 1, 'b': 2}
>>> con.close()
```

The following row factory returns a *named tuple*:

```
from collections import namedtuple

def namedtuple_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    cls = namedtuple("Row", fields)
    return cls._make(row)
```

`namedtuple_factory()` can be used as follows:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = namedtuple_factory
>>> cur = con.execute("SELECT 1 AS a, 2 AS b")
>>> row = cur.fetchone()
>>> row
Row(a=1, b=2)
>>> row[0]  # Indexed access.
1
>>> row.b   # Attribute access.
2
>>> con.close()
```

With some adjustments, the above recipe can be adapted to use a *dataclass*, or any other custom class, instead of a *namedtuple*.

How to handle non-UTF-8 text encodings

By default, `sqlite3` uses *str* to adapt SQLite values with the `TEXT` data type. This works well for UTF-8 encoded text, but it might fail for other encodings and invalid UTF-8. You can use a custom *text_factory* to handle such cases.

Because of SQLite's flexible typing, it is not uncommon to encounter table columns with the `TEXT` data type containing non-UTF-8 encodings, or even arbitrary data. To demonstrate, let's assume we have a database with ISO-8859-2

(Latin-2) encoded text, for example a table of Czech-English dictionary entries. Assuming we now have a *Connection* instance `con` connected to this database, we can decode the Latin-2 encoded text using this *text_factory*:

```
con.text_factory = lambda data: str(data, encoding="latin2")
```

For invalid UTF-8 or arbitrary data in stored in `TEXT` table columns, you can use the following technique, borrowed from the unicode-howto:

```
con.text_factory = lambda data: str(data, errors="surrogateescape")
```

Note

The `sqlite3` module API does not support strings containing surrogates.

unicode-howto

12.6.4 Explanation

Transaction control

`sqlite3` offers multiple methods of controlling whether, when and how database transactions are opened and closed. *Transaction control via the autocommit attribute* is recommended, while *Transaction control via the isolation_level attribute* retains the pre-Python 3.12 behaviour.

Transaction control via the `autocommit` attribute

The recommended way of controlling transaction behaviour is through the *Connection.autocommit* attribute, which should preferably be set using the *autocommit* parameter of *connect()*.

It is suggested to set *autocommit* to `False`, which implies **PEP 249**-compliant transaction control. This means:

- `sqlite3` ensures that a transaction is always open, so *connect()*, *Connection.commit()*, and *Connection.rollback()* will implicitly open a new transaction (immediately after closing the pending one, for the latter two). `sqlite3` uses `BEGIN DEFERRED` statements when opening transactions.
- Transactions should be committed explicitly using `commit()`.
- Transactions should be rolled back explicitly using `rollback()`.
- An implicit rollback is performed if the database is *close()*-ed with pending changes.

Set *autocommit* to `True` to enable SQLite's autocommit mode. In this mode, *Connection.commit()* and *Connection.rollback()* have no effect. Note that SQLite's autocommit mode is distinct from the **PEP 249**-compliant *Connection.autocommit* attribute; use *Connection.in_transaction* to query the low-level SQLite autocommit mode.

Set *autocommit* to *LEGACY_TRANSACTION_CONTROL* to leave transaction control behaviour to the *Connection.isolation_level* attribute. See *Transaction control via the isolation_level attribute* for more information.

Transaction control via the `isolation_level` attribute

Note

The recommended way of controlling transactions is via the *autocommit* attribute. See *Transaction control via the autocommit attribute*.

If *Connection.autocommit* is set to *LEGACY_TRANSACTION_CONTROL* (the default), transaction behaviour is controlled using the *Connection.isolation_level* attribute. Otherwise, `isolation_level` has no effect.

If the connection attribute *isolation_level* is not `None`, new transactions are implicitly opened before *execute()* and *executemany()* executes `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statements; for other statements, no implicit transaction handling is performed. Use the *commit()* and *rollback()* methods to respectively commit and roll back pending transactions. You can choose the underlying SQLite transaction behaviour — that is, whether and what type of `BEGIN` statements `sqlite3` implicitly executes – via the *isolation_level* attribute.

If *isolation_level* is set to `None`, no transactions are implicitly opened at all. This leaves the underlying SQLite library in autocommit mode, but also allows the user to perform their own transaction handling using explicit SQL statements. The underlying SQLite library autocommit mode can be queried using the *in_transaction* attribute.

The *executescript()* method implicitly commits any pending transaction before execution of the given SQL script, regardless of the value of *isolation_level*.

Changed in version 3.6: `sqlite3` used to implicitly commit an open transaction before DDL statements. This is no longer the case.

Changed in version 3.12: The recommended way of controlling transactions is now via the *autocommit* attribute.

CHAPTER

THIRTEEN

DATA COMPRESSION AND ARCHIVING

The modules described in this chapter support data compression with the zlib, gzip, bzip2 and lzma algorithms, and the creation of ZIP- and tar-format archives. See also *Archiving operations* provided by the `shutil` module.

13.1 `zlib` — Compression compatible with `gzip`

For applications that require data compression, the functions in this module allow compression and decompression, using the zlib library. The zlib library has its own home page at https://www.zlib.net. There are known incompatibilities between the Python module and versions of the zlib library earlier than 1.1.3; 1.1.3 has a security vulnerability, so we recommend using 1.1.4 or later.

zlib's functions have many options and often need to be used in a particular order. This documentation doesn't attempt to cover all of the permutations; consult the zlib manual at http://www.zlib.net/manual.html for authoritative information.

For reading and writing `.gz` files see the `gzip` module.

The available exception and functions in this module are:

exception zlib.**error**

Exception raised on compression and decompression errors.

zlib.**adler32**(*data*[, *value*])

Computes an Adler-32 checksum of *data*. (An Adler-32 checksum is almost as reliable as a CRC32 but can be computed much more quickly.) The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 1 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

Changed in version 3.0: The result is always unsigned.

zlib.**compress**(*data*, */*, *level=-1*, *wbits=MAX_WBITS*)

Compresses the bytes in *data*, returning a bytes object containing compressed data. *level* is an integer from `0` to `9` or `-1` controlling the level of compression; `1` (Z_BEST_SPEED) is fastest and produces the least compression, `9` (Z_BEST_COMPRESSION) is slowest and produces the most. `0` (Z_NO_COMPRESSION) is no compression. The default value is `-1` (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

The *wbits* argument controls the size of the history buffer (or the "window size") used when compressing data, and whether a header and trailer is included in the output. It can take several ranges of values, defaulting to `15` (MAX_WBITS):

- +9 to +15: The base-two logarithm of the window size, which therefore ranges between 512 and 32768. Larger values produce better compression at the expense of greater memory usage. The resulting output will include a zlib-specific header and trailer.

- −9 to −15: Uses the absolute value of *wbits* as the window size logarithm, while producing a raw output stream with no header or trailing checksum.
- +25 to +31 = 16 + (9 to 15): Uses the low 4 bits of the value as the window size logarithm, while including a basic **gzip** header and trailing checksum in the output.

Raises the `error` exception if any error occurs.

Changed in version 3.6: *level* can now be used as a keyword parameter.

Changed in version 3.11: The *wbits* parameter is now available to set window bits and compression type.

zlib.**compressobj**(*level=-1*, *method=DEFLATED*, *wbits=MAX_WBITS*, *memLevel=DEF_MEM_LEVEL*, *strategy=Z_DEFAULT_STRATEGY*[, *zdict*])

Returns a compression object, to be used for compressing data streams that won't fit into memory at once.

level is the compression level – an integer from `0` to `9` or `-1`. A value of `1` (Z_BEST_SPEED) is fastest and produces the least compression, while a value of `9` (Z_BEST_COMPRESSION) is slowest and produces the most. `0` (Z_NO_COMPRESSION) is no compression. The default value is `-1` (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

method is the compression algorithm. Currently, the only supported value is `DEFLATED`.

The *wbits* parameter controls the size of the history buffer (or the "window size"), and what header and trailer format will be used. It has the same meaning as *described for compress()*.

The *memLevel* argument controls the amount of memory used for the internal compression state. Valid values range from `1` to `9`. Higher values use more memory, but are faster and produce smaller output.

strategy is used to tune the compression algorithm. Possible values are `Z_DEFAULT_STRATEGY`, `Z_FILTERED`, `Z_HUFFMAN_ONLY`, `Z_RLE` (zlib 1.2.0.1) and `Z_FIXED` (zlib 1.2.2.2).

zdict is a predefined compression dictionary. This is a sequence of bytes (such as a `bytes` object) containing subsequences that are expected to occur frequently in the data that is to be compressed. Those subsequences that are expected to be most common should come at the end of the dictionary.

Changed in version 3.3: Added the *zdict* parameter and keyword argument support.

zlib.**crc32**(*data*[, *value*])

Computes a CRC (Cyclic Redundancy Check) checksum of *data*. The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 0 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

Changed in version 3.0: The result is always unsigned.

zlib.**decompress**(*data*, */*, *wbits=MAX_WBITS*, *bufsize=DEF_BUF_SIZE*)

Decompresses the bytes in *data*, returning a bytes object containing the uncompressed data. The *wbits* parameter depends on the format of *data*, and is discussed further below. If *bufsize* is given, it is used as the initial size of the output buffer. Raises the `error` exception if any error occurs.

The *wbits* parameter controls the size of the history buffer (or "window size"), and what header and trailer format is expected. It is similar to the parameter for `compressobj()`, but accepts more ranges of values:

- +8 to +15: The base-two logarithm of the window size. The input must include a zlib header and trailer.
- 0: Automatically determine the window size from the zlib header. Only supported since zlib 1.2.3.5.
- −8 to −15: Uses the absolute value of *wbits* as the window size logarithm. The input must be a raw stream with no header or trailer.
- +24 to +31 = 16 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm. The input must include a gzip header and trailer.
- +40 to +47 = 32 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm, and automatically accepts either the zlib or gzip format.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an `error` exception. The default *wbits* value corresponds to the largest window size and requires a zlib header and trailer to be included.

bufsize is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to `malloc()`.

Changed in version 3.6: *wbits* and *bufsize* can be used as keyword arguments.

`zlib.`**`decompressobj`**`(`*wbits=MAX_WBITS*[, *zdict*]`)`

Returns a decompression object, to be used for decompressing data streams that won't fit into memory at once.

The *wbits* parameter controls the size of the history buffer (or the "window size"), and what header and trailer format is expected. It has the same meaning as *described for decompress()*.

The *zdict* parameter specifies a predefined compression dictionary. If provided, this must be the same dictionary as was used by the compressor that produced the data that is to be decompressed.

> **Note**
>
> If *zdict* is a mutable object (such as a `bytearray`), you must not modify its contents between the call to `decompressobj()` and the first call to the decompressor's `decompress()` method.

Changed in version 3.3: Added the *zdict* parameter.

Compression objects support the following methods:

`Compress.`**`compress`**`(`*data*`)`

Compress *data*, returning a bytes object containing compressed data for at least part of the data in *data*. This data should be concatenated to the output produced by any preceding calls to the `compress()` method. Some input may be kept in internal buffers for later processing.

`Compress.`**`flush`**`(`[*mode*]`)`

All pending input is processed, and a bytes object containing the remaining compressed output is returned. *mode* can be selected from the constants `Z_NO_FLUSH`, `Z_PARTIAL_FLUSH`, `Z_SYNC_FLUSH`, `Z_FULL_FLUSH`, `Z_BLOCK` (zlib 1.2.3.4), or `Z_FINISH`, defaulting to `Z_FINISH`. Except `Z_FINISH`, all constants allow compressing further bytestrings of data, while `Z_FINISH` finishes the compressed stream and prevents compressing any more data. After calling `flush()` with *mode* set to `Z_FINISH`, the `compress()` method cannot be called again; the only realistic action is to delete the object.

`Compress.`**`copy`**`()`

Returns a copy of the compression object. This can be used to efficiently compress a set of data that share a common initial prefix.

Changed in version 3.8: Added `copy.copy()` and `copy.deepcopy()` support to compression objects.

Decompression objects support the following methods and attributes:

`Decompress.`**`unused_data`**

A bytes object which contains any bytes past the end of the compressed data. That is, this remains `b""` until the last byte that contains compression data is available. If the whole bytestring turned out to contain compressed data, this is `b""`, an empty bytes object.

`Decompress.`**`unconsumed_tail`**

A bytes object that contains any data that was not consumed by the last `decompress()` call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent `decompress()` method call in order to get correct output.

Decompress.**eof**

A boolean indicating whether the end of the compressed data stream has been reached.

This makes it possible to distinguish between a properly formed compressed stream, and an incomplete or truncated one.

Added in version 3.3.

Decompress.**decompress**(*data*, *max_length=0*)

Decompress *data*, returning a bytes object containing the uncompressed data corresponding to at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the *decompress()* method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max_length* is non-zero then the return value will be no longer than *max_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute *unconsumed_tail*. This bytestring must be passed to a subsequent call to *decompress()* if decompression is to continue. If *max_length* is zero then the whole input is decompressed, and *unconsumed_tail* is empty.

Changed in version 3.6: *max_length* can be used as a keyword argument.

Decompress.**flush**([*length*])

All pending input is processed, and a bytes object containing the remaining uncompressed output is returned. After calling *flush()*, the *decompress()* method cannot be called again; the only realistic action is to delete the object.

The optional parameter *length* sets the initial size of the output buffer.

Decompress.**copy**()

Returns a copy of the decompression object. This can be used to save the state of the decompressor midway through the data stream in order to speed up random seeks into the stream at a future point.

Changed in version 3.8: Added *copy.copy()* and *copy.deepcopy()* support to decompression objects.

Information about the version of the zlib library in use is available through the following constants:

zlib.**ZLIB_VERSION**

The version string of the zlib library that was used for building the module. This may be different from the zlib library actually used at runtime, which is available as *ZLIB_RUNTIME_VERSION*.

zlib.**ZLIB_RUNTIME_VERSION**

The version string of the zlib library actually loaded by the interpreter.

Added in version 3.3.

13.2 gzip — Support for gzip files

Source code: Lib/gzip.py

This module provides a simple interface to compress and decompress files just like the GNU programs **gzip** and **gunzip** would.

The data compression is provided by the *zlib* module.

The *gzip* module provides the *GzipFile* class, as well as the *open()*, *compress()* and *decompress()* convenience functions. The *GzipFile* class reads and writes **gzip**-format files, automatically compressing or decompressing the data so that it looks like an ordinary *file object*.

Note that additional file formats which can be decompressed by the **gzip** and **gunzip** programs, such as those produced by **compress** and **pack**, are not supported by this module.

The module defines the following items:

gzip.**open**(*filename*, *mode='rb'*, *compresslevel=9*, *encoding=None*, *errors=None*, *newline=None*)

Open a gzip-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'` or `'xb'` for binary mode, or `'rt'`, `'at'`, `'wt'`, or `'xt'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 0 to 9, as for the *GzipFile* constructor.

For binary mode, this function is equivalent to the *GzipFile* constructor: `GzipFile(filename, mode, compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *GzipFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

Changed in version 3.3: Added support for *filename* being a file object, support for text mode, and the *encoding*, *errors* and *newline* arguments.

Changed in version 3.4: Added support for the `'x'`, `'xb'` and `'xt'` modes.

Changed in version 3.6: Accepts a *path-like object*.

exception gzip.**BadGzipFile**

An exception raised for invalid gzip files. It inherits from *OSError*. *EOFError* and *zlib.error* can also be raised for invalid gzip files.

Added in version 3.8.

class gzip.**GzipFile**(*filename=None*, *mode=None*, *compresslevel=9*, *fileobj=None*, *mtime=None*)

Constructor for the *GzipFile* class, which simulates most of the methods of a *file object*, with the exception of the *truncate()* method. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, an *io.BytesIO* object, or any other object which simulates a file. It defaults to `None`, in which case *filename* is opened to provide a file object.

When *fileobj* is not `None`, the *filename* argument is only used to be included in the **gzip** file header, which may include the original filename of the uncompressed file. It defaults to the filename of *fileobj*, if discernible; otherwise, it defaults to the empty string, and in this case the original filename is not included in the header.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'`, or `'xb'`, depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is `'rb'`. In future Python releases the mode of *fileobj* will not be used. It is better to always specify *mode* for writing.

Note that the file is always opened in binary mode. To open a compressed file in text mode, use *open()* (or wrap your *GzipFile* with an *io.TextIOWrapper*).

The *compresslevel* argument is an integer from `0` to `9` controlling the level of compression; `1` is fastest and produces the least compression, and `9` is slowest and produces the most compression. `0` is no compression. The default is `9`.

The optional *mtime* argument is the timestamp requested by gzip. The time is in Unix format, i.e., seconds since 00:00:00 UTC, January 1, 1970. If *mtime* is omitted or `None`, the current time is used. Use *mtime* = 0 to generate a compressed stream that does not depend on creation time.

See below for the *mtime* attribute that is set when decompressing.

Calling a *GzipFile* object's `close()` method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass an *io.BytesIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *io.BytesIO* object's *getvalue()* method.

GzipFile supports the *io.BufferedIOBase* interface, including iteration and the `with` statement. Only the *truncate()* method isn't implemented.

GzipFile also provides the following method and attribute:

peek(*n*)

Read *n* uncompressed bytes without advancing the file position. The number of bytes returned may be more or less than requested.

> **Note**
>
> While calling *peek()* does not change the file position of the *GzipFile*, it may change the position of the underlying file object (e.g. if the *GzipFile* was constructed with the *fileobj* parameter).

Added in version 3.2.

mode

`'rb'` for reading and `'wb'` for writing.

Changed in version 3.13: In previous versions it was an integer `1` or `2`.

mtime

When decompressing, this attribute is set to the last timestamp in the most recently read header. It is an integer, holding the number of seconds since the Unix epoch (00:00:00 UTC, January 1, 1970). The initial value before reading any headers is `None`.

name

The path to the gzip file on disk, as a *str* or *bytes*. Equivalent to the output of *os.fspath()* on the original input path, with no other normalization, resolution or expansion.

Changed in version 3.1: Support for the `with` statement was added, along with the *mtime* constructor argument and *mtime* attribute.

Changed in version 3.2: Support for zero-padded and unseekable files was added.

Changed in version 3.3: The *io.BufferedIOBase.read1()* method is now implemented.

Changed in version 3.4: Added support for the `'x'` and `'xb'` modes.

Changed in version 3.5: Added support for writing arbitrary *bytes-like objects*. The *read()* method now accepts an argument of `None`.

Changed in version 3.6: Accepts a *path-like object*.

Deprecated since version 3.9: Opening *GzipFile* for writing without specifying the *mode* argument is deprecated.

Changed in version 3.12: Remove the `filename` attribute, use the *name* attribute instead.

gzip.**compress**(*data*, *compresslevel=9*, *, *mtime=None*)

Compress the *data*, returning a `bytes` object containing the compressed data. *compresslevel* and *mtime* have the same meaning as in the `GzipFile` constructor above.

Added in version 3.2.

Changed in version 3.8: Added the *mtime* parameter for reproducible output.

Changed in version 3.11: Speed is improved by compressing all data at once instead of in a streamed fashion. Calls with *mtime* set to `0` are delegated to `zlib.compress()` for better speed. In this situation the output may contain a gzip header "OS" byte value other than 255 "unknown" as supplied by the underlying zlib implementation.

Changed in version 3.13: The gzip header OS byte is guaranteed to be set to 255 when this function is used as was the case in 3.10 and earlier.

gzip.**decompress**(*data*)

Decompress the *data*, returning a `bytes` object containing the uncompressed data. This function is capable of decompressing multi-member gzip data (multiple gzip blocks concatenated together). When the data is certain to contain only one member the `zlib.decompress()` function with *wbits* set to 31 is faster.

Added in version 3.2.

Changed in version 3.11: Speed is improved by decompressing members at once in memory instead of in a streamed fashion.

13.2.1 Examples of usage

Example of how to read a compressed file:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

Example of how to create a compressed GZIP file:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

Example of how to GZIP compress an existing file:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

Example of how to GZIP compress a binary string:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

See also

Module *zlib*
The basic data compression module needed to support the **gzip** file format.

In case gzip (de)compression is a bottleneck, the python-isal package speeds up (de)compression with a mostly compatible API.

13.2.2 Command Line Interface

The *gzip* module provides a simple command line interface to compress or decompress files.

Once executed the *gzip* module keeps the input file(s).

Changed in version 3.8: Add a new command line interface with a usage. By default, when you will execute the CLI, the default compression level is 6.

Command line options

file

If *file* is not specified, read from *sys.stdin*.

--fast

Indicates the fastest compression method (less compression).

--best

Indicates the slowest compression method (best compression).

-d, --decompress

Decompress the given file.

-h, --help

Show the help message.

13.3 bz2 — Support for bzip2 compression

Source code: Lib/bz2.py

This module provides a comprehensive interface for compressing and decompressing data using the bzip2 compression algorithm.

The *bz2* module contains:

- The *open()* function and *BZ2File* class for reading and writing compressed files.
- The *BZ2Compressor* and *BZ2Decompressor* classes for incremental (de)compression.
- The *compress()* and *decompress()* functions for one-shot (de)compression.

13.3.1 (De)compression of files

bz2.**open**(*filename*, *mode='rb'*, *compresslevel=9*, *encoding=None*, *errors=None*, *newline=None*)

Open a bzip2-compressed file in binary or text mode, returning a *file object*.

As with the constructor for *BZ2File*, the *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'w'`, `'wb'`, `'x'`, `'xb'`, `'a'` or `'ab'` for binary mode, or `'rt'`, `'wt'`, `'xt'`, or `'at'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 1 to 9, as for the *BZ2File* constructor.

For binary mode, this function is equivalent to the *BZ2File* constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *BZ2File* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

Added in version 3.3.

Changed in version 3.4: The `'x'` (exclusive creation) mode was added.

Changed in version 3.6: Accepts a *path-like object*.

class bz2.**BZ2File**(*filename*, *mode='r'*, *, *compresslevel=9*)

Open a bzip2-compressed file in binary mode.

If *filename* is a *str* or *bytes* object, open the named file directly. Otherwise, *filename* should be a *file object*, which will be used to read or write the compressed data.

The *mode* argument can be either `'r'` for reading (default), `'w'` for overwriting, `'x'` for exclusive creation, or `'a'` for appending. These can equivalently be given as `'rb'`, `'wb'`, `'xb'` and `'ab'` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `'w'` does not truncate the file, and is instead equivalent to `'a'`.

If *mode* is `'w'` or `'a'`, *compresslevel* can be an integer between `1` and `9` specifying the level of compression: `1` produces the least compression, and `9` (default) produces the most compression.

If *mode* is `'r'`, the input file may be the concatenation of multiple compressed streams.

BZ2File provides all of the members specified by the *io.BufferedIOBase*, except for *detach()* and *truncate()*. Iteration and the `with` statement are supported.

BZ2File also provides the following methods and attributes:

peek([*n*])

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

> **Note**
>
> While calling *peek()* does not change the file position of the *BZ2File*, it may change the position of the underlying file object (e.g. if the *BZ2File* was constructed by passing a file object for *filename*).

Added in version 3.3.

fileno()

Return the file descriptor for the underlying file.

Added in version 3.3.

readable()

Return whether the file was opened for reading.

Added in version 3.3.

seekable()

Return whether the file supports seeking.

Added in version 3.3.

writable()

Return whether the file was opened for writing.

Added in version 3.3.

read1(*size=-1*)

Read up to *size* uncompressed bytes, while trying to avoid making multiple reads from the underlying stream. Reads up to a buffer's worth of data if size is negative.

Returns `b''` if the file is at EOF.

Added in version 3.3.

readinto(*b*)

Read bytes into *b*.

Returns the number of bytes read (0 for EOF).

Added in version 3.3.

mode

`'rb'` for reading and `'wb'` for writing.

Added in version 3.13.

name

The bzip2 file name. Equivalent to the `name` attribute of the underlying *file object*.

Added in version 3.13.

Changed in version 3.1: Support for the `with` statement was added.

Changed in version 3.3: Support was added for *filename* being a *file object* instead of an actual filename.

The `'a'` (append) mode was added, along with support for reading multi-stream files.

Changed in version 3.4: The `'x'` (exclusive creation) mode was added.

Changed in version 3.5: The `read()` method now accepts an argument of `None`.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.9: The *buffering* parameter has been removed. It was ignored and deprecated since Python 3.0. Pass an open file object to control how the file is opened.

The *compresslevel* parameter became keyword-only.

Changed in version 3.10: This class is thread unsafe in the face of multiple simultaneous readers or writers, just like its equivalent classes in `gzip` and `lzma` have always been.

13.3.2 Incremental (de)compression

class bz2.**BZ2Compressor**(*compresslevel=9*)

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the `compress()` function instead.

compresslevel, if given, must be an integer between `1` and `9`. The default is `9`.

compress(*data*)

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the `flush()` method to finish the compression process.

flush()

Finish the compression process. Returns the compressed data left in internal buffers.

The compressor object may not be used after this method has been called.

class bz2.**BZ2Decompressor**

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot compression, use the `decompress()` function instead.

> **Note**
>
> This class does not transparently handle inputs containing multiple compressed streams, unlike *decompress()* and *BZ2File*. If you need to decompress a multi-stream input with *BZ2Decompressor*, you must use a new decompressor for each stream.

decompress(*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to *decompress()*. The returned data should be concatenated with the output of any previous calls to *decompress()*.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to `False`. In this case, the next call to *decompress()* may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an *EOFError*. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

Changed in version 3.5: Added the *max_length* parameter.

eof

`True` if the end-of-stream marker has been reached.

Added in version 3.3.

unused_data

Data found after the end of the compressed stream.

If this attribute is accessed before the end of the stream has been reached, its value will be `b''`.

needs_input

`False` if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

Added in version 3.5.

13.3.3 One-shot (de)compression

`bz2.`**compress**(*data*, *compresslevel=9*)

Compress *data*, a *bytes-like object*.

compresslevel, if given, must be an integer between `1` and `9`. The default is `9`.

For incremental compression, use a *BZ2Compressor* instead.

`bz2.`**decompress**(*data*)

Decompress *data*, a *bytes-like object*.

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a *BZ2Decompressor* instead.

Changed in version 3.3: Support for multi-stream inputs was added.

13.3.4 Examples of usage

Below are some examples of typical usage of the *bz2* module.

Using *compress()* and *decompress()* to demonstrate round-trip compression:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> c = bz2.compress(data)
>>> len(data) / len(c)  # Data compression ratio
1.513595166163142
>>> d = bz2.decompress(c)
>>> data == d  # Check equality to original object after round-trip
True
```

Using *BZ2Compressor* for incremental compression:

```
>>> import bz2
>>> def gen_data(chunks=10, chunksize=1000):
...     """Yield incremental blocks of chunksize bytes."""
...     for _ in range(chunks):
...         yield b"z" * chunksize
...
>>> comp = bz2.BZ2Compressor()
>>> out = b""
>>> for chunk in gen_data():
...     # Provide data to the compressor object
...     out = out + comp.compress(chunk)
...
>>> # Finish the compression process.  Call this once you have
>>> # finished providing data to the compressor.
>>> out = out + comp.flush()
```

The example above uses a very "nonrandom" stream of data (a stream of `b"z"` chunks). Random data tends to compress poorly, while ordered, repetitive data usually yields a high compression ratio.

Writing and reading a bzip2-compressed file in binary mode:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> with bz2.open("myfile.bz2", "wb") as f:
...     # Write compressed data to file
...     unused = f.write(data)
...
>>> with bz2.open("myfile.bz2", "rb") as f:
...     # Decompress data from file
...     content = f.read()
...
>>> content == data  # Check equality to original object after round-trip
True
```

13.4 lzma — Compression using the LZMA algorithm

Added in version 3.3.

Source code: Lib/lzma.py

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the `.xz` and legacy `.lzma` file formats used by the **xz** utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the *bz2* module. Note that *LZMAFile* and *bz2.BZ2File* are *not* thread-safe, so if you need to use a single *LZMAFile* instance from multiple threads, it is necessary to protect it with a lock.

exception lzma.**LZMAError**

This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

13.4.1 Reading and writing compressed files

lzma.**open**(*filename*, *mode='rb'*, ***, *format=None*, *check=-1*, *preset=None*, *filters=None*, *encoding=None*, *errors=None*, *newline=None*)

Open an LZMA-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be either an actual file name (given as a *str*, *bytes* or *path-like* object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of `"r"`, `"rb"`, `"w"`, `"wb"`, `"x"`, `"xb"`, `"a"` or `"ab"` for binary mode, or `"rt"`, `"wt"`, `"xt"`, or `"at"` for text mode. The default is `"rb"`.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

For binary mode, this function is equivalent to the *LZMAFile* constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *LZMAFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

Changed in version 3.4: Added support for the `"x"`, `"xb"` and `"xt"` modes.

Changed in version 3.6: Accepts a *path-like object*.

class lzma.**LZMAFile**(*filename=None*, *mode='r'*, ***, *format=None*, *check=-1*, *preset=None*, *filters=None*)

Open an LZMA-compressed file in binary mode.

An *LZMAFile* can wrap an already-open *file object*, or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a *str*, *bytes* or *path-like* object). When wrapping an existing file object, the wrapped file will not be closed when the *LZMAFile* is closed.

The *mode* argument can be either `"r"` for reading (default), `"w"` for overwriting, `"x"` for exclusive creation, or `"a"` for appending. These can equivalently be given as `"rb"`, `"wb"`, `"xb"` and `"ab"` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `"w"` does not truncate the file, and is instead equivalent to `"a"`.

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

LZMAFile supports all the members specified by *io.BufferedIOBase*, except for *detach()* and *truncate()*. Iteration and the `with` statement are supported.

The following method and attributes are also provided:

peek(*size=-1*)

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

> **Note**
>
> While calling *peek()* does not change the file position of the *LZMAFile*, it may change the position of the underlying file object (e.g. if the *LZMAFile* was constructed by passing a file object for *filename*).

mode

`'rb'` for reading and `'wb'` for writing.

Added in version 3.13.

name

The lzma file name. Equivalent to the *name* attribute of the underlying *file object*.

Added in version 3.13.

Changed in version 3.4: Added support for the `"x"` and `"xb"` modes.

Changed in version 3.5: The *read()* method now accepts an argument of `None`.

Changed in version 3.6: Accepts a *path-like object*.

13.4.2 Compressing and decompressing data in memory

class lzma.**LZMACompressor**(*format=FORMAT_XZ*, *check=-1*, *preset=None*, *filters=None*)

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see *compress()*.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT_XZ: The `.xz` container format.**
  This is the default format.
- **FORMAT_ALONE: The legacy `.lzma` container format.**
  This format is more limited than `.xz` – it does not support integrity checks or multiple filters.
- **FORMAT_RAW: A raw data stream, not using any container format.**
  This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and decompression). Additionally, data compressed in this manner cannot be decompressed using `FORMAT_AUTO` (see *LZMADecompressor*).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- `CHECK_NONE`: No integrity check. This is the default (and the only acceptable value) for `FORMAT_ALONE` and `FORMAT_RAW`.
- `CHECK_CRC32`: 32-bit Cyclic Redundancy Check.
- `CHECK_CRC64`: 64-bit Cyclic Redundancy Check. This is the default for `FORMAT_XZ`.
- `CHECK_SHA256`: 256-bit Secure Hash Algorithm.

If the specified check is not supported, an *LZMAError* is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between `0` and `9` (inclusive), optionally OR-ed with the constant `PRESET_EXTREME`. If neither *preset* nor *filters* are given, the default behavior is to use `PRESET_DEFAULT` (preset level `6`). Higher presets produce smaller output, but make the compression process slower.

> **Note**
>
> In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset `9` for example, the overhead for an *LZMACompressor* object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See *Specifying custom filter chains* for details.

compress(*data*)

Compress *data* (a *bytes* object), returning a *bytes* object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to *compress()* and *flush()*. The returned data should be concatenated with the output of any previous calls to *compress()*.

flush()

Finish the compression process, returning a *bytes* object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

class lzma.**LZMADecompressor**(*format=FORMAT_AUTO*, *memlimit=None*, *filters=None*)

Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see *decompress()*.

The *format* argument specifies the container format that should be used. The default is `FORMAT_AUTO`, which can decompress both `.xz` and `.lzma` files. Other possible values are `FORMAT_XZ`, `FORMAT_ALONE`, and `FORMAT_RAW`.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an *LZMAError* if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to create the stream being decompressed. This argument is required if *format* is `FORMAT_RAW`, but should not be used for other formats. See *Specifying custom filter chains* for more information about filter chains.

> **Note**
>
> This class does not transparently handle inputs containing multiple compressed streams, unlike *decompress()* and *LZMAFile*. To decompress a multi-stream input with *LZMADecompressor*, you must create a new decompressor for each stream.

decompress(*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to *decompress()*. The returned data should be concatenated with the output of any previous calls to *decompress()*.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to `False`. In this case, the next call to *decompress()* may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an *EOFError*. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

Changed in version 3.5: Added the *max_length* parameter.

check

The ID of the integrity check used by the input stream. This may be `CHECK_UNKNOWN` until enough of the input has been decoded to determine what integrity check it uses.

eof

`True` if the end-of-stream marker has been reached.

unused_data

Data found after the end of the compressed stream.

Before the end of the stream is reached, this will be `b""`.

needs_input

`False` if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

Added in version 3.5.

`lzma.`**compress**(*data*, *format=FORMAT_XZ*, *check=-1*, *preset=None*, *filters=None*)

Compress *data* (a *bytes* object), returning the compressed data as a *bytes* object.

See *LZMACompressor* above for a description of the *format*, *check*, *preset* and *filters* arguments.

`lzma.`**decompress**(*data*, *format=FORMAT_AUTO*, *memlimit=None*, *filters=None*)

Decompress *data* (a *bytes* object), returning the uncompressed data as a *bytes* object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See *LZMADecompressor* above for a description of the *format*, *memlimit* and *filters* arguments.

13.4.3 Miscellaneous

`lzma.`**is_check_supported**(*check*)

Return `True` if the given integrity check is supported on this system.

`CHECK_NONE` and `CHECK_CRC32` are always supported. `CHECK_CRC64` and `CHECK_SHA256` may be unavailable if you are using a version of **liblzma** that was compiled with a limited feature set.

13.4.4 Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key `"id"`, and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- Compression filters:
  - `FILTER_LZMA1` (for use with `FORMAT_ALONE`)
  - `FILTER_LZMA2` (for use with `FORMAT_XZ` and `FORMAT_RAW`)
- Delta filter:
  - `FILTER_DELTA`

- Branch-Call-Jump (BCJ) filters:
  - FILTER_X86
  - FILTER_IA64
  - FILTER_ARM
  - FILTER_ARMTHUMB
  - FILTER_POWERPC
  - FILTER_SPARC

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- preset: A compression preset to use as a source of default values for options that are not specified explicitly.
- dict_size: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- lc: Number of literal context bits.
- lp: Number of literal position bits. The sum lc + lp must be at most 4.
- pb: Number of position bits; must be at most 4.
- mode: MODE_FAST or MODE_NORMAL.
- nice_len: What should be considered a "nice length" for a match. This should be 273 or less.
- mf: What match finder to use – MF_HC3, MF_HC4, MF_BT2, MF_BT3, or MF_BT4.
- depth: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, dist. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, start_offset. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

13.4.5 Examples

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_EXTREME},
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

13.5 `zipfile` — Work with ZIP archives

Source code: Lib/zipfile/

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in PKZIP Application Note.

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GiB in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

exception zipfile.**BadZipFile**

The error raised for bad ZIP files.

Added in version 3.2.

exception zipfile.**BadZipfile**

Alias of *BadZipFile*, for compatibility with older Python versions.

Deprecated since version 3.2.

exception zipfile.**LargeZipFile**

The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

class zipfile.**ZipFile**

The class for reading and writing ZIP files. See section *ZipFile Objects* for constructor details.

class zipfile.**Path**

Class that implements a subset of the interface provided by `pathlib.Path`, including the full `importlib.resources.abc.Traversable` interface.

Added in version 3.8.

class zipfile.**PyZipFile**

Class for creating ZIP archives containing Python libraries.

class zipfile.**ZipInfo**(*filename='NoName'*, *date_time=(1980, 1, 1, 0, 0, 0)*)

Class used to represent information about a member of an archive. Instances of this class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Most users of the `zipfile` module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section *ZipInfo Objects*.

Changed in version 3.13: A public `compress_level` attribute has been added to expose the formerly protected `_compresslevel`. The older protected name continues to work as a property for backwards compatibility.

zipfile.**is_zipfile**(*filename*)

Returns `True` if *filename* is a valid ZIP file based on its magic number, otherwise returns `False`. *filename* may be a file or file-like object too.

Changed in version 3.1: Support for file and file-like objects.

zipfile.**ZIP_STORED**

The numeric constant for an uncompressed archive member.

zipfile.**ZIP_DEFLATED**

The numeric constant for the usual ZIP compression method. This requires the `zlib` module.

zipfile.**ZIP_BZIP2**

The numeric constant for the BZIP2 compression method. This requires the `bz2` module.

Added in version 3.3.

zipfile.**ZIP_LZMA**

The numeric constant for the LZMA compression method. This requires the `lzma` module.

Added in version 3.3.

Note

The ZIP file format specification has included support for bzip2 compression since 2001, and for LZMA compression since 2006. However, some tools (including older Python releases) do not support these compression methods, and may either refuse to process the ZIP file altogether, or fail to extract individual files.

See also

PKZIP Application Note
Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

Info-ZIP Home Page
Information about the Info-ZIP project's ZIP archive programs and development libraries.

13.5.1 ZipFile Objects

class zipfile.**ZipFile**(*file*, *mode='r'*, *compression=ZIP_STORED*, *allowZip64=True*, *compresslevel=None*, ***, *strict_timestamps=True*, *metadata_encoding=None*)

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a *path-like object*.

The *mode* parameter should be `'r'` to read an existing file, `'w'` to truncate and write a new file, `'a'` to append to an existing file, or `'x'` to exclusively create and write a new file. If *mode* is `'x'` and *file* refers to an existing file, a `FileExistsError` will be raised. If *mode* is `'a'` and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is `'a'` and the file does not exist at all, it is created. If *mode* is `'r'` or `'a'`, the file should be seekable.

compression is the ZIP compression method to use when writing the archive, and should be `ZIP_STORED`, `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA`; unrecognized values will cause `NotImplementedError` to be raised. If `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` is specified but the corresponding module (`zlib`, `bz2` or `lzma`) is not available, `RuntimeError` is raised. The default is `ZIP_STORED`.

If *allowZip64* is `True` (the default) zipfile will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 4 GiB. If it is `false` `zipfile` will raise an exception when the ZIP file would require ZIP64 extensions.

The *compresslevel* parameter controls the compression level to use when writing files to the archive. When using `ZIP_STORED` or `ZIP_LZMA` it has no effect. When using `ZIP_DEFLATED` integers `0` through `9` are accepted (see `zlib` for more information). When using `ZIP_BZIP2` integers `1` through `9` are accepted (see `bz2` for more information).

The *strict_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

When mode is `'r'`, *metadata_encoding* may be set to the name of a codec, which will be used to decode metadata such as the names of members and ZIP comments.

If the file is created with mode `'w'`, `'x'` or `'a'` and then `closed` without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

ZipFile is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

> **Note**
>
> *metadata_encoding* is an instance-wide setting for the ZipFile. It is not currently possible to set this on a per-member basis.
>
> This attribute is a workaround for legacy implementations which produce archives with names in the current locale encoding or code page (mostly on Windows). According to the .ZIP standard, the encoding of metadata may be specified to be either IBM code page (default) or UTF-8 by a flag in the archive header. That flag takes precedence over *metadata_encoding*, which is a Python-specific extension.

Changed in version 3.2: Added the ability to use `ZipFile` as a context manager.

Changed in version 3.3: Added support for `bzip2` and `lzma` compression.

Changed in version 3.4: ZIP64 extensions are enabled by default.

Changed in version 3.5: Added support for writing to unseekable streams. Added support for the `'x'` mode.

Changed in version 3.6: Previously, a plain `RuntimeError` was raised for unrecognized compression values.

Changed in version 3.6.2: The *file* parameter accepts a *path-like object*.

Changed in version 3.7: Add the *compresslevel* parameter.

Changed in version 3.8: The *strict_timestamps* keyword-only parameter.

Changed in version 3.11: Added support for specifying member name encoding for reading metadata in the zipfile's directory and file headers.

`ZipFile.`**`close`**`()`

Close the archive file. You must call *close()* before exiting your program or essential records will not be written.

`ZipFile.`**`getinfo`**`(`*name*`)`

Return a *ZipInfo* object with information about the archive member *name*. Calling *getinfo()* for a name not currently contained in the archive will raise a *KeyError*.

`ZipFile.`**`infolist`**`()`

Return a list containing a *ZipInfo* object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.`**`namelist`**`()`

Return a list of archive members by name.

`ZipFile.`**`open`**`(`*name*, *mode='r'*, *pwd=None*, ***, *force_zip64=False*`)`

Access a member of the archive as a binary file-like object. *name* can be either the name of a file within the archive or a *ZipInfo* object. The *mode* parameter, if included, must be `'r'` (the default) or `'w'`. *pwd* is the password used to decrypt encrypted ZIP files as a *bytes* object.

open() is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With *mode* `'r'` the file-like object (`ZipExtFile`) is read-only and provides the following methods: *read()*, *readline()*, *readlines()*, *seek()*, *tell()*, *__iter__()*, *__next__()*. These objects can operate independently of the ZipFile.

With `mode='w'`, a writable file handle is returned, which supports the *write()* method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a *ValueError*.

In both cases the file-like object has also attributes `name`, which is equivalent to the name of a file within the archive, and `mode`, which is `'rb'` or `'wb'` depending on the input mode.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass `force_zip64=True` to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a *ZipInfo* object with *file_size* set, and use that as the *name* parameter.

> **Note**
>
> The *open()*, *read()* and *extract()* methods can take a filename or a *ZipInfo* object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

Changed in version 3.6: Removed support of `mode='U'`. Use *io.TextIOWrapper* for reading compressed text files in *universal newlines* mode.

Changed in version 3.6: *ZipFile.open()* can now be used to write files into the archive with the `mode='w'` option.

Changed in version 3.6: Calling *open()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

Changed in version 3.13: Added attributes `name` and `mode` for the writeable file-like object. The value of the `mode` attribute for the readable file-like object was changed from `'r'` to `'rb'`.

ZipFile.**extract**(*member*, *path=None*, *pwd=None*)

Extract a member from the archive to the current working directory; *member* must be its full name or a *ZipInfo* object. Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a *ZipInfo* object. *pwd* is the password used for encrypted files as a *bytes* object.

Returns the normalized path created (a directory or new file).

> **Note**
>
> If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `"..."` components in a member filename will be removed, e.g.: `../../foo../../ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (_).

Changed in version 3.6: Calling *extract()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

Changed in version 3.6.2: The *path* parameter accepts a *path-like object*.

ZipFile.**extractall**(*path=None*, *members=None*, *pwd=None*)

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by *namelist()*. *pwd* is the password used for encrypted files as a *bytes* object.

> **Warning**
>
> Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`. This module attempts to prevent that. See *extract()* note.

Changed in version 3.6: Calling *extractall()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

Changed in version 3.6.2: The *path* parameter accepts a *path-like object*.

ZipFile.**printdir**()

Print a table of contents for the archive to `sys.stdout`.

ZipFile.**setpassword**(*pwd*)

Set *pwd* (a *bytes* object) as default password to extract encrypted files.

ZipFile.**read**(*name*, *pwd=None*)

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a *ZipInfo* object. The archive must be open for read or append. *pwd* is the password used for encrypted files as a *bytes* object and, if specified, overrides the default password set with *setpassword()*. Calling *read()* on a ZipFile that uses a compression method other than *ZIP_STORED*, *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA* will raise a *NotImplementedError*. An error will also be raised if the corresponding compression module is not available.

Changed in version 3.6: Calling *read()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**testzip**()

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`.

Changed in version 3.6: Calling *testzip()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**write**(*filename*, *arcname=None*, *compress_type=None*, *compresslevel=None*)

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry. Similarly, *compresslevel* will override the constructor if given. The archive must be open with mode `'w'`, `'x'` or `'a'`.

> **Note**
>
> The ZIP file standard historically did not specify a metadata encoding, but strongly recommended CP437 (the original IBM PC encoding) for interoperability. Recent versions allow use of UTF-8 (only). In this module, UTF-8 will automatically be used to write the member names if they contain any non-ASCII characters. It is not possible to write member names in any encoding other than ASCII or UTF-8.

> **Note**
>
> Archive names should be relative to the archive root, that is, they should not start with a path separator.

> **Note**
>
> If `arcname` (or `filename`, if `arcname` is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

> **Note**
>
> A leading slash in the filename may lead to the archive being impossible to open in some zip programs on Windows systems.

Changed in version 3.6: Calling *write()* on a ZipFile created with mode `'r'` or a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**writestr**(*zinfo_or_arcname*, *data*, *compress_type=None*, *compresslevel=None*)

Write a file into the archive. The contents is *data*, which may be either a *str* or a *bytes* instance; if it is a *str*, it is encoded as UTF-8 first. *zinfo_or_arcname* is either the file name it will be given in the archive, or a *ZipInfo* instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode `'w'`, `'x'` or `'a'`.

If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry, or in the *zinfo_or_arcname* (if that is a *ZipInfo* instance). Similarly, *compresslevel* will override the constructor if given.

> **Note**
>
> When passing a *ZipInfo* instance as the *zinfo_or_arcname* parameter, the compression method used will be that specified in the *compress_type* member of the given *ZipInfo* instance. By default, the *ZipInfo* constructor sets this member to *ZIP_STORED*.

Changed in version 3.2: The *compress_type* argument.

Changed in version 3.6: Calling *writestr()* on a ZipFile created with mode `'r'` or a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**mkdir**(*zinfo_or_directory*, *mode=511*)

Create a directory inside the archive. If *zinfo_or_directory* is a string, a directory is created inside the archive

with the mode that is specified in the *mode* argument. If, however, *zinfo_or_directory* is a `ZipInfo` instance then the *mode* argument is ignored.

The archive must be opened with mode `'w'`, `'x'` or `'a'`.

Added in version 3.11.

The following data attributes are also available:

`ZipFile.`**`filename`**

Name of the ZIP file.

`ZipFile.`**`debug`**

The level of debug output to use. This may be set from `0` (the default, no output) to `3` (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.`**`comment`**

The comment associated with the ZIP file as a `bytes` object. If assigning a comment to a `ZipFile` instance created with mode `'w'`, `'x'` or `'a'`, it should be no longer than 65535 bytes. Comments longer than this will be truncated.

13.5.2 Path Objects

`class` `zipfile.`**`Path`**(*root*, *at=''*)

Construct a Path object from a `root` zipfile (which may be a `ZipFile` instance or `file` suitable for passing to the `ZipFile` constructor).

`at` specifies the location of this Path within the zipfile, e.g. 'dir/file.txt', 'dir/', or ''. Defaults to the empty string, indicating the root.

> **Note**
>
> The `Path` class does not sanitize filenames within the ZIP archive. Unlike the `ZipFile.extract()` and `ZipFile.extractall()` methods, it is the caller's responsibility to validate or sanitize filenames to prevent path traversal vulnerabilities (e.g., filenames containing ".." or absolute paths). When handling untrusted archives, consider resolving filenames using `os.path.abspath()` and checking against the target directory with `os.path.commonpath()`.

Path objects expose the following features of `pathlib.Path` objects:

Path objects are traversable using the `/` operator or `joinpath`.

`Path.`**`name`**

The final path component.

`Path.`**`open`**(*mode='r'*, ***, *pwd*, ****)

Invoke `ZipFile.open()` on the current path. Allows opening for read or write, text or binary through supported modes: 'r', 'w', 'rb', 'wb'. Positional and keyword arguments are passed through to `io.TextIOWrapper` when opened as text and ignored otherwise. `pwd` is the `pwd` parameter to `ZipFile.open()`.

Changed in version 3.9: Added support for text and binary modes for open. Default mode is now text.

Changed in version 3.11.2: The `encoding` parameter can be supplied as a positional argument without causing a `TypeError`. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all `io.TextIOWrapper` arguments, `encoding` included, as keywords.

`Path.`**`iterdir`**()

Enumerate the children of the current directory.

`Path.`**`is_dir`**()

Return `True` if the current context references a directory.

Path.**is_file**()

Return `True` if the current context references a file.

Path.**is_symlink**()

Return `True` if the current context references a symbolic link.

Added in version 3.12.

Changed in version 3.13: Previously, `is_symlink` would unconditionally return `False`.

Path.**exists**()

Return `True` if the current context references a file or directory in the zip file.

Path.**suffix**

The last dot-separated portion of the final component, if any. This is commonly called the file extension.

Added in version 3.11: Added *Path.suffix* property.

Path.**stem**

The final path component, without its suffix.

Added in version 3.11: Added *Path.stem* property.

Path.**suffixes**

A list of the path's suffixes, commonly called file extensions.

Added in version 3.11: Added *Path.suffixes* property.

Path.**read_text**(*, **)

Read the current file as unicode text. Positional and keyword arguments are passed through to *io.TextIOWrapper* (except `buffer`, which is implied by the context).

Changed in version 3.11.2: The `encoding` parameter can be supplied as a positional argument without causing a *TypeError*. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all *io.TextIOWrapper* arguments, `encoding` included, as keywords.

Path.**read_bytes**()

Read the current file as bytes.

Path.**joinpath**(**other*)

Return a new Path object with each of the *other* arguments joined. The following are equivalent:

```
>>> Path(...).joinpath('child').joinpath('grandchild')
>>> Path(...).joinpath('child', 'grandchild')
>>> Path(...) / 'child' / 'grandchild'
```

Changed in version 3.10: Prior to 3.10, `joinpath` was undocumented and accepted exactly one parameter.

The zipp project provides backports of the latest path object functionality to older Pythons. Use `zipp.Path` in place of `zipfile.Path` for early access to changes.

13.5.3 PyZipFile Objects

The *PyZipFile* constructor takes the same parameters as the *ZipFile* constructor, and one additional parameter, *optimize*.

class zipfile.**PyZipFile**(*file*, *mode='r'*, *compression=ZIP_STORED*, *allowZip64=True*, *optimize=-1*)

Changed in version 3.2: Added the *optimize* parameter.

Changed in version 3.4: ZIP64 extensions are enabled by default.

Instances have one method in addition to those of *ZipFile* objects:

writepy(*pathname*, *basename=''*, *filterfunc=None*)

Search for files `*.py` and add the corresponding file to the archive.

If the *optimize* parameter to *PyZipFile* was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the *optimize* parameter to *PyZipFile* was `0`, `1` or `2`, only files with that optimization level (see *compile()*) are added to the archive, compiling if necessary.

If *pathname* is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If *pathname* is a file that does not end with `.py`, a *RuntimeError* will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively in sorted order.

basename is intended for internal use only.

filterfunc, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If *filterfunc* returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in `test` directories or start with the string `test_`, we can use a *filterfunc* to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
...
>>> zf.writepy('myprog', filterfunc=notests)
```

The *writepy()* method makes archives with file names like this:

```
string.pyc                    # Top level name
test/__init__.pyc             # Package directory
test/testall.pyc              # Module test.testall
test/bogus/__init__.pyc       # Subpackage directory
test/bogus/myfile.pyc         # Submodule test.bogus.myfile
```

Changed in version 3.4: Added the *filterfunc* parameter.

Changed in version 3.6.2: The *pathname* parameter accepts a *path-like object*.

Changed in version 3.7: Recursion sorts directory entries.

13.5.4 ZipInfo Objects

Instances of the *ZipInfo* class are returned by the *getinfo()* and *infolist()* methods of *ZipFile* objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a *ZipInfo* instance for a filesystem file:

classmethod ZipInfo.**from_file**(*filename*, *arcname=None*, *, *strict_timestamps=True*)

Construct a *ZipInfo* instance for a file on the filesystem, in preparation for adding it to a zip file.

filename should be the path to a file or directory on the filesystem.

If *arcname* is specified, it is used as the name within the archive. If *arcname* is not specified, the name will be the same as *filename*, but with any drive letter and leading path separators removed.

The *strict_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

Added in version 3.6.

Changed in version 3.6.2: The *filename* parameter accepts a *path-like object*.

Changed in version 3.8: Added the *strict_timestamps* keyword-only parameter.

Instances have the following methods and attributes:

`ZipInfo.is_dir()`

Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

Added in version 3.6.

`ZipInfo.filename`

Name of the file in the archive.

`ZipInfo.date_time`

The time and date of the last modification to the archive member. This is a tuple of six values:

Index	Value
0	Year (>= 1980)
1	Month (one-based)
2	Day of month (one-based)
3	Hours (zero-based)
4	Minutes (zero-based)
5	Seconds (zero-based)

Note

The ZIP file format does not support timestamps before 1980.

`ZipInfo.compress_type`

Type of compression for the archive member.

`ZipInfo.comment`

Comment for the individual archive member as a `bytes` object.

`ZipInfo.extra`

Expansion field data. The PKZIP Application Note contains some comments on the internal structure of the data contained in this `bytes` object.

`ZipInfo.create_system`

System which created ZIP archive.

`ZipInfo.create_version`

PKZIP version which created ZIP archive.

`ZipInfo.extract_version`

PKZIP version needed to extract archive.

`ZipInfo.reserved`

Must be zero.

`ZipInfo.flag_bits`

ZIP flag bits.

`ZipInfo.volume`

Volume number of file header.

ZipInfo.**internal_attr**
: Internal attributes.

ZipInfo.**external_attr**
: External file attributes.

ZipInfo.**header_offset**
: Byte offset to the file header.

ZipInfo.**CRC**
: CRC-32 of the uncompressed file.

ZipInfo.**compress_size**
: Size of the compressed data.

ZipInfo.**file_size**
: Size of the uncompressed file.

13.5.5 Command-Line Interface

The *zipfile* module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the *-c* option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the *-e* option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the *-l* option:

```
$ python -m zipfile -l monty.zip
```

Command-line options

-l <zipfile>

--list <zipfile>
: List files in a zipfile.

-c <zipfile> <source1> ... <sourceN>

--create <zipfile> <source1> ... <sourceN>
: Create zipfile from source files.

-e <zipfile> <output_dir>

--extract <zipfile> <output_dir>
: Extract zipfile into target directory.

-t <zipfile>

--test <zipfile>
: Test whether the zipfile is valid or not.

--metadata-encoding <encoding>
: Specify encoding of member names for *-l*, *-e* and *-t*.

  Added in version 3.11.

13.5.6 Decompression pitfalls

The extraction in zipfile module might fail due to some pitfalls listed below.

From file itself

Decompression may fail due to incorrect password / CRC checksum / ZIP format or unsupported compression method / decryption.

File System limitations

Exceeding limitations on different file systems can cause decompression failed. Such as allowable characters in the directory entries, length of the file name, length of the pathname, size of a single file, and number of files, etc.

Resources limitations

The lack of memory or disk volume would lead to decompression failed. For example, decompression bombs (aka ZIP bomb) apply to zipfile library that can cause disk volume exhaustion.

Interruption

Interruption during the decompression, such as pressing control-C or killing the decompression process may result in incomplete decompression of the archive.

Default behaviors of extraction

Not knowing the default extraction behaviors can cause unexpected decompression results. For example, when extracting the same archive twice, it overwrites files without asking.

13.6 `tarfile` — Read and write tar archive files

Source code: Lib/tarfile.py

The `tarfile` module makes it possible to read and write tar archives, including those using gzip, bz2 and lzma compression. Use the `zipfile` module to read or write `.zip` files, or the higher-level functions in *shutil*.

Some facts and figures:

- reads and writes `gzip`, `bz2` and `lzma` compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for all variants of the *sparse* extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

Changed in version 3.3: Added support for `lzma` compression.

Changed in version 3.12: Archives are extracted using a *filter*, which makes it possible to either limit surprising/dangerous features, or to acknowledge that they are expected and the archive is fully trusted. By default, archives are fully trusted, but this default is deprecated and slated to change in Python 3.14.

`tarfile.`**`open`**(*name=None*, *mode='r'*, *fileobj=None*, *bufsize=10240*, ***kwargs*)

Return a `TarFile` object for the pathname *name*. For detailed information on `TarFile` objects and the keyword arguments that are allowed, see *TarFile Objects*.

mode has to be a string of the form `'filemode[:compression]'`, it defaults to `'r'`. Here is a full list of mode combinations:

mode	action
`'r'` or `'r:*'`	Open for reading with transparent compression (recommended).
`'r:'`	Open for reading exclusively without compression.
`'r:gz'`	Open for reading with gzip compression.
`'r:bz2'`	Open for reading with bzip2 compression.
`'r:xz'`	Open for reading with lzma compression.
`'x'` or `'x:'`	Create a tarfile exclusively without compression. Raise a *FileExistsError* exception if it already exists.
`'x:gz'`	Create a tarfile with gzip compression. Raise a *FileExistsError* exception if it already exists.
`'x:bz2'`	Create a tarfile with bzip2 compression. Raise a *FileExistsError* exception if it already exists.
`'x:xz'`	Create a tarfile with lzma compression. Raise a *FileExistsError* exception if it already exists.
`'a'` or `'a:'`	Open for appending with no compression. The file is created if it does not exist.
`'w'` or `'w:'`	Open for uncompressed writing.
`'w:gz'`	Open for gzip compressed writing.
`'w:bz2'`	Open for bzip2 compressed writing.
`'w:xz'`	Open for lzma compressed writing.

Note that `'a:gz'`, `'a:bz2'` or `'a:xz'` is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, *ReadError* is raised. Use *mode* `'r'` to avoid this. If a compression method is not supported, *CompressionError* is raised.

If *fileobj* is specified, it is used as an alternative to a *file object* opened in binary mode for *name*. It is supposed to be at position 0.

For modes `'w:gz'`, `'x:gz'`, `'w|gz'`, `'w:bz2'`, `'x:bz2'`, `'w|bz2'`, *tarfile.open()* accepts the keyword argument *compresslevel* (default `9`) to specify the compression level of the file.

For modes `'w:xz'` and `'x:xz'`, *tarfile.open()* accepts the keyword argument *preset* to specify the compression level of the file.

For special purposes, there is a second format for *mode*: `'filemode|[compression]'`. *tarfile.open()* will return a *TarFile* object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a *read()* or *write()* method (depending on the *mode*) that works with bytes. *bufsize* specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin.buffer`, a socket *file object* or a tape device. However, such a *TarFile* object is limited in that it does not allow random access, see *Examples*. The currently possible modes:

Mode	Action
`'r|*'`	Open a *stream* of tar blocks for reading with transparent compression.
`'r|'`	Open a *stream* of uncompressed tar blocks for reading.
`'r|gz'`	Open a gzip compressed *stream* for reading.
`'r|bz2'`	Open a bzip2 compressed *stream* for reading.
`'r|xz'`	Open an lzma compressed *stream* for reading.
`'w|'`	Open an uncompressed *stream* for writing.
`'w|gz'`	Open a gzip compressed *stream* for writing.
`'w|bz2'`	Open a bzip2 compressed *stream* for writing.
`'w|xz'`	Open an lzma compressed *stream* for writing.

Changed in version 3.5: The `'x'` (exclusive creation) mode was added.

Changed in version 3.6: The *name* parameter accepts a *path-like object*.

Changed in version 3.12: The *compresslevel* keyword argument also works for streams.

class tarfile.**TarFile**

Class for reading and writing tar archives. Do not use this class directly: use `tarfile.open()` instead. See *TarFile Objects*.

tarfile.**is_tarfile**(*name*)

Return `True` if *name* is a tar archive file, that the `tarfile` module can read. *name* may be a `str`, file, or file-like object.

Changed in version 3.9: Support for file and file-like objects.

The `tarfile` module defines the following exceptions:

exception tarfile.**TarError**

Base class for all `tarfile` exceptions.

exception tarfile.**ReadError**

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

exception tarfile.**CompressionError**

Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception tarfile.**StreamError**

Is raised for the limitations that are typical for stream-like `TarFile` objects.

exception tarfile.**ExtractError**

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel== 2`.

exception tarfile.**HeaderError**

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

exception tarfile.**FilterError**

Base class for members *refused* by filters.

tarinfo

Information about the member that the filter refused to extract, as *TarInfo*.

exception tarfile.**AbsolutePathError**

Raised to refuse extracting a member with an absolute path.

exception tarfile.**OutsideDestinationError**

Raised to refuse extracting a member outside the destination directory.

exception tarfile.**SpecialFileError**

Raised to refuse extracting a special file (e.g. a device or pipe).

exception tarfile.**AbsoluteLinkError**

Raised to refuse extracting a symbolic link with an absolute path.

exception tarfile.**LinkOutsideDestinationError**

Raised to refuse extracting a symbolic link pointing outside the destination directory.

exception tarfile.**LinkFallbackError**

Raised to refuse emulating a link (hard or symbolic) by extracting another archive member, when that member would be rejected by the filter location. The exception that was raised to reject the replacement member is available as `BaseException.__context__`.

Added in version 3.13.4.

The following constants are available at the module level:

tarfile.**ENCODING**

The default character encoding: `'utf-8'` on Windows, the value returned by *sys.getfilesystemencoding()* otherwise.

tarfile.**REGTYPE**

tarfile.**AREGTYPE**

A regular file *type*.

tarfile.**LNKTYPE**

A link (inside tarfile) *type*.

tarfile.**SYMTYPE**

A symbolic link *type*.

tarfile.**CHRTYPE**

A character special device *type*.

tarfile.**BLKTYPE**

A block special device *type*.

tarfile.**DIRTYPE**

A directory *type*.

tarfile.**FIFOTYPE**

A FIFO special device *type*.

tarfile.**CONTTYPE**

A contiguous file *type*.

tarfile.**GNUTYPE_LONGNAME**

A GNU tar longname *type*.

tarfile.**GNUTYPE_LONGLINK**

A GNU tar longlink *type*.

tarfile.**GNUTYPE_SPARSE**

A GNU tar sparse file *type*.

Each of the following constants defines a tar archive format that the *tarfile* module is able to create. See section *Supported tar formats* for details.

tarfile.**USTAR_FORMAT**

POSIX.1-1988 (ustar) format.

tarfile.**GNU_FORMAT**

GNU tar format.

tarfile.**PAX_FORMAT**

POSIX.1-2001 (pax) format.

tarfile.**DEFAULT_FORMAT**

The default format for creating archives. This is currently *PAX_FORMAT*.

Changed in version 3.8: The default format for new archives was changed to *PAX_FORMAT* from *GNU_FORMAT*.

13.6.1 TarFile Objects

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see *TarInfo Objects* for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the *Examples* section for a use case.

Added in version 3.2: Added support for the context management protocol.

class tarfile.**TarFile**(*name=None*, *mode='r'*, *fileobj=None*, *format=DEFAULT_FORMAT*, *tarinfo=TarInfo*, *dereference=False*, *ignore_zeros=False*, *encoding=ENCODING*, *errors='surrogateescape'*, *pax_headers=None*, *debug=0*, *errorlevel=1*, *stream=False*)

All following arguments are optional and can be accessed as instance attributes as well.

name is the pathname of the archive. *name* may be a *path-like object*. It can be omitted if *fileobj* is given. In this case, the file object's `name` attribute is used if it exists.

mode is either `'r'` to read from an existing archive, `'a'` to append data to an existing file, `'w'` to create a new file overwriting an existing one, or `'x'` to create a new file only if it does not already exist.

If *fileobj* is given, it is used for reading or writing data. If it can be determined, *mode* is overridden by *fileobj*'s mode. *fileobj* will be used from position 0.

Note

fileobj is not closed, when `TarFile` is closed.

format controls the archive format for writing. It must be one of the constants `USTAR_FORMAT`, `GNU_FORMAT` or `PAX_FORMAT` that are defined at module level. When reading, format will be automatically detected, even if different formats are present in a single archive.

The *tarinfo* argument can be used to replace the default `TarInfo` class with a different one.

If *dereference* is `False`, add symbolic and hard links to the archive. If it is `True`, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore_zeros* is `False`, treat an empty block as the end of the archive. If it is `True`, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

debug can be set from `0` (no debug messages) up to `3` (all debug messages). The messages are written to `sys.stderr`.

errorlevel controls how extraction errors are handled, see `the corresponding attribute`.

The *encoding* and *errors* arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section *Unicode issues* for in-depth information.

The *pax_headers* argument is an optional dictionary of strings which will be added as a pax global header if *format* is `PAX_FORMAT`.

If *stream* is set to `True` then while reading the archive info about files in the archive are not cached, saving memory.

Changed in version 3.2: Use `'surrogateescape'` as the default for the *errors* argument.

Changed in version 3.5: The `'x'` (exclusive creation) mode was added.

Changed in version 3.6: The *name* parameter accepts a *path-like object*.

Changed in version 3.13: Add the *stream* parameter.

classmethod TarFile.**open**(...)

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

TarFile.**getmember**(*name*)

Return a `TarInfo` object for member *name*. If *name* can not be found in the archive, `KeyError` is raised.

> **Note**
>
> If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

TarFile.**getmembers**()

Return the members of the archive as a list of `TarInfo` objects. The list has the same order as the members in the archive.

TarFile.**getnames**()

Return the members as a list of their names. It has the same order as the list returned by `getmembers()`.

TarFile.**list**(*verbose=True*, *, *members=None*)

Print a table of contents to `sys.stdout`. If *verbose* is `False`, only the names of the members are printed. If it is `True`, output similar to that of **`ls -l`** is produced. If optional *members* is given, it must be a subset of the list returned by `getmembers()`.

Changed in version 3.5: Added the *members* parameter.

TarFile.**next**()

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

TarFile.**extractall**(*path='.'*, *members=None*, *, *numeric_owner=False*, *filter=None*)

Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If *numeric_owner* is `True`, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

The *filter* argument specifies how `members` are modified or rejected before extraction. See *Extraction filters* for details. It is recommended to set this explicitly depending on which *tar* features you need to support.

> **Warning**
>
> Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`.
>
> Set `filter='data'` to prevent the most dangerous security issues, and read the *Extraction filters* section for details.

Changed in version 3.5: Added the *numeric_owner* parameter.

Changed in version 3.6: The *path* parameter accepts a *path-like object*.

Changed in version 3.12: Added the *filter* parameter.

TarFile.**extract**(*member*, *path=''*, *set_attrs=True*, ***, *numeric_owner=False*, *filter=None*)

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a `TarInfo` object. You can specify a different directory using *path*. *path* may be a *path-like object*. File attributes (owner, mtime, mode) are set unless *set_attrs* is false.

The *numeric_owner* and *filter* arguments are the same as for `extractall()`.

Note

The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

Warning

See the warning for `extractall()`.

Set `filter='data'` to prevent the most dangerous security issues, and read the *Extraction filters* section for details.

Changed in version 3.2: Added the *set_attrs* parameter.

Changed in version 3.5: Added the *numeric_owner* parameter.

Changed in version 3.6: The *path* parameter accepts a *path-like object*.

Changed in version 3.12: Added the *filter* parameter.

TarFile.**extractfile**(*member*)

Extract a member from the archive as a file object. *member* may be a filename or a `TarInfo` object. If *member* is a regular file or a link, an `io.BufferedReader` object is returned. For all other existing members, `None` is returned. If *member* does not appear in the archive, `KeyError` is raised.

Changed in version 3.3: Return an `io.BufferedReader` object.

Changed in version 3.13: The returned `io.BufferedReader` object has the `mode` attribute which is always equal to `'rb'`.

TarFile.**errorlevel**: *int*

If *errorlevel* is `0`, errors are ignored when using `TarFile.extract()` and `TarFile.extractall()`. Nevertheless, they appear as error messages in the debug output when *debug* is greater than 0. If `1` (the default), all *fatal* errors are raised as `OSError` or `FilterError` exceptions. If `2`, all *non-fatal* errors are raised as `TarError` exceptions as well.

Some exceptions, e.g. ones caused by wrong argument types or data corruption, are always raised.

Custom *extraction filters* should raise `FilterError` for *fatal* errors and `ExtractError` for *non-fatal* ones.

Note that when an exception is raised, the archive may be partially extracted. It is the user's responsibility to clean up.

TarFile.**extraction_filter**

Added in version 3.12.

The *extraction filter* used as a default for the *filter* argument of `extract()` and `extractall()`.

The attribute may be `None` or a callable. String names are not allowed for this attribute, unlike the *filter* argument to `extract()`.

If `extraction_filter` is `None` (the default), calling an extraction method without a *filter* argument will raise a `DeprecationWarning`, and fall back to the `fully_trusted` filter, whose dangerous behavior matches previous versions of Python.

In Python 3.14+, leaving `extraction_filter=None` will cause extraction methods to use the *data* filter by default.

The attribute may be set on instances or overridden in subclasses. It also is possible to set it on the `TarFile` class itself to set a global default, although, since it affects all uses of *tarfile*, it is best practice to only do so in top-level applications or *site configuration*. To set a global default this way, a filter function needs to be wrapped in *staticmethod()* to prevent injection of a `self` argument.

`TarFile.`**`add`**(*name*, *arcname=None*, *recursive=True*, *, *filter=None*)

Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to *False*. Recursion adds entries in sorted order. If *filter* is given, it should be a function that takes a *TarInfo* object argument and returns the changed *TarInfo* object. If it instead returns *None* the *TarInfo* object will be excluded from the archive. See *Examples* for an example.

Changed in version 3.2: Added the *filter* parameter.

Changed in version 3.7: Recursion adds entries in sorted order.

`TarFile.`**`addfile`**(*tarinfo*, *fileobj=None*)

Add the *TarInfo* object *tarinfo* to the archive. If *tarinfo* represents a non zero-size regular file, the *fileobj* argument should be a *binary file*, and `tarinfo.size` bytes are read from it and added to the archive. You can create *TarInfo* objects directly, or by using *gettarinfo()*.

Changed in version 3.13: *fileobj* must be given for non-zero-sized regular files.

`TarFile.`**`gettarinfo`**(*name=None*, *arcname=None*, *fileobj=None*)

Create a *TarInfo* object from the result of *os.stat()* or equivalent on an existing file. The file is either named by *name*, or specified as a *file object* *fileobj* with a file descriptor. *name* may be a *path-like object*. If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s *name* attribute, or the *name* argument. The name should be a text string.

You can modify some of the *TarInfo*'s attributes before you add it using *addfile()*. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as *size* may need modifying. This is the case for objects such as *GzipFile*. The *name* may also be modified, in which case *arcname* could be a dummy string.

Changed in version 3.6: The *name* parameter accepts a *path-like object*.

`TarFile.`**`close`**()

Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

`TarFile.`**`pax_headers`**`: `***`dict`***

A dictionary containing key-value pairs of pax global headers.

13.6.2 TarInfo Objects

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

TarInfo objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettarinfo()*.

Modifying the objects returned by *getmember()* or *getmembers()* will affect all subsequent operations on the archive. For cases where this is unwanted, you can use *copy.copy()* or call the *replace()* method to create a modified copy in one step.

Several attributes can be set to `None` to indicate that a piece of metadata is unused or unknown. Different *TarInfo* methods handle `None` differently:

- The *extract()* or *extractall()* methods will ignore the corresponding metadata, leaving it set to a default.
- *addfile()* will fail.
- *list()* will print a placeholder string.

class tarfile.**TarInfo**(*name=''*)

Create a *TarInfo* object.

classmethod TarInfo.**frombuf**(*buf*, *encoding*, *errors*)

Create and return a *TarInfo* object from string buffer *buf*.

Raises *HeaderError* if the buffer is invalid.

classmethod TarInfo.**fromtarfile**(*tarfile*)

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

TarInfo.**tobuf**(*format=DEFAULT_FORMAT*, *encoding=ENCODING*, *errors='surrogateescape'*)

Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

Changed in version 3.2: Use `'surrogateescape'` as the default for the *errors* argument.

A `TarInfo` object has the following public data attributes:

TarInfo.**name**: ***str***

Name of the archive member.

TarInfo.**size**: ***int***

Size in bytes.

TarInfo.**mtime**: ***int*** | ***float***

Time of last modification in seconds since the *epoch*, as in *os.stat_result.st_mtime*.

Changed in version 3.12: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**mode**: ***int***

Permission bits, as for *os.chmod()*.

Changed in version 3.12: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**type**

File type. *type* is usually one of these constants: *REGTYPE*, *AREGTYPE*, *LNKTYPE*, *SYMTYPE*, *DIRTYPE*, *FIFOTYPE*, *CONTTYPE*, *CHRTYPE*, *BLKTYPE*, *GNUTYPE_SPARSE*. To determine the type of a *TarInfo* object more conveniently, use the `is*()` methods below.

TarInfo.**linkname**: ***str***

Name of the target file name, which is only present in *TarInfo* objects of type *LNKTYPE* and *SYMTYPE*.

For symbolic links (`SYMTYPE`), the *linkname* is relative to the directory that contains the link. For hard links (`LNKTYPE`), the *linkname* is relative to the root of the archive.

TarInfo.**uid**: ***int***

User ID of the user who originally stored this member.

Changed in version 3.12: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**gid**: ***int***

Group ID of the user who originally stored this member.

Changed in version 3.12: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**uname**: ***str***

User name.

Changed in version 3.12: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**gname**: *str*

Group name.

Changed in version 3.12: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**chksum**: *int*

Header checksum.

TarInfo.**devmajor**: *int*

Device major number.

TarInfo.**devminor**: *int*

Device minor number.

TarInfo.**offset**: *int*

The tar header starts here.

TarInfo.**offset_data**: *int*

The file's data starts here.

TarInfo.**sparse**

Sparse member information.

TarInfo.**pax_headers**: *dict*

A dictionary containing key-value pairs of an associated pax extended header.

TarInfo.**replace**(*name=...*, *mtime=...*, *mode=...*, *linkname=...*, *uid=...*, *gid=...*, *uname=...*, *gname=...*, *deep=True*)

Added in version 3.12.

Return a *new* copy of the `TarInfo` object with the given attributes changed. For example, to return a `TarInfo` with the group name set to `'staff'`, use:

```
new_tarinfo = old_tarinfo.replace(gname='staff')
```

By default, a deep copy is made. If *deep* is false, the copy is shallow, i.e. `pax_headers` and any custom attributes are shared with the original `TarInfo` object.

A *TarInfo* object also provides some convenient query methods:

TarInfo.**isfile**()

Return *True* if the *TarInfo* object is a regular file.

TarInfo.**isreg**()

Same as *isfile()*.

TarInfo.**isdir**()

Return *True* if it is a directory.

TarInfo.**issym**()

Return *True* if it is a symbolic link.

TarInfo.**islnk**()

Return *True* if it is a hard link.

TarInfo.**ischr**()

Return *True* if it is a character device.

TarInfo.**isblk**()

Return *True* if it is a block device.

TarInfo.**isfifo**()

Return *True* if it is a FIFO.

TarInfo.**isdev**()

Return *True* if it is one of character device, block device or FIFO.

13.6.3 Extraction filters

Added in version 3.12.

The *tar* format is designed to capture all details of a UNIX-like filesystem, which makes it very powerful. Unfortunately, the features make it easy to create tar files that have unintended – and possibly malicious – effects when extracted. For example, extracting a tar file can overwrite arbitrary files in various ways (e.g. by using absolute paths, `..` path components, or symlinks that affect later members).

In most cases, the full functionality is not needed. Therefore, *tarfile* supports extraction filters: a mechanism to limit functionality, and thus mitigate some of the security issues.

See also

PEP 706
Contains further motivation and rationale behind the design.

The *filter* argument to *TarFile.extract()* or *extractall()* can be:

- the string `'fully_trusted'`: Honor all metadata as specified in the archive. Should be used if the user trusts the archive completely, or implements their own complex verification.
- the string `'tar'`: Honor most *tar*-specific features (i.e. features of UNIX-like filesystems), but block features that are very likely to be surprising or malicious. See *tar_filter()* for details.
- the string `'data'`: Ignore or block most features specific to UNIX-like filesystems. Intended for extracting cross-platform data archives. See *data_filter()* for details.
- `None` (default): Use *TarFile.extraction_filter*.

  If that is also `None` (the default), raise a `DeprecationWarning`, and fall back to the `'fully_trusted'` filter, whose dangerous behavior matches previous versions of Python.

  In Python 3.14, the `'data'` filter will become the default instead. It's possible to switch earlier; see *TarFile.extraction_filter*.

- A callable which will be called for each extracted member with a *TarInfo* describing the member and the destination path to where the archive is extracted (i.e. the same path is used for all members):

  ```
  filter(member: TarInfo, path: str, /) -> TarInfo | None
  ```

  The callable is called just before each member is extracted, so it can take the current state of the disk into account. It can:

  - return a *TarInfo* object which will be used instead of the metadata in the archive, or
  - return `None`, in which case the member will be skipped, or
  - raise an exception to abort the operation or skip the member, depending on *errorlevel*. Note that when extraction is aborted, *extractall()* may leave the archive partially extracted. It does not attempt to clean up.

Default named filters

The pre-defined, named filters are available as functions, so they can be reused in custom filters:

tarfile.**fully_trusted_filter**(*member*, *path*)

Return *member* unchanged.

This implements the `'fully_trusted'` filter.

tarfile.**tar_filter**(*member*, *path*)

Implements the `'tar'` filter.

- Strip leading slashes (`/` and *os.sep*) from filenames.
- *Refuse* to extract files with absolute paths (in case the name is absolute even after stripping slashes, e.g. `C:/foo` on Windows). This raises *AbsolutePathError*.
- *Refuse* to extract files whose absolute path (after following symlinks) would end up outside the destination. This raises *OutsideDestinationError*.
- Clear high mode bits (setuid, setgid, sticky) and group/other write bits (*S_IWGRP* | *S_IWOTH*).

Return the modified `TarInfo` member.

tarfile.**data_filter**(*member*, *path*)

Implements the `'data'` filter. In addition to what `tar_filter` does:

- Normalize link targets (*TarInfo.linkname*) using *os.path.normpath()*. Note that this removes internal `..` components, which may change the meaning of the link if the path in `TarInfo.linkname` traverses symbolic links.
- *Refuse* to extract links (hard or soft) that link to absolute paths, or ones that link outside the destination.

  This raises *AbsoluteLinkError* or *LinkOutsideDestinationError*.

  Note that such files are refused even on platforms that do not support symbolic links.
- *Refuse* to extract device files (including pipes). This raises *SpecialFileError*.
- For regular files, including hard links:
  - Set the owner read and write permissions (*S_IRUSR* | *S_IWUSR*).
  - Remove the group & other executable permission (*S_IXGRP* | *S_IXOTH*) if the owner doesn't have it (*S_IXUSR*).
- For other files (directories), set `mode` to `None`, so that extraction methods skip applying permission bits.
- Set user and group info (`uid`, `gid`, `uname`, `gname`) to `None`, so that extraction methods skip setting it.

Return the modified `TarInfo` member.

Changed in version 3.13.4: Link targets are now normalized.

Filter errors

When a filter refuses to extract a file, it will raise an appropriate exception, a subclass of *FilterError*. This will abort the extraction if *TarFile.errorlevel* is 1 or more. With `errorlevel=0` the error will be logged and the member will be skipped, but extraction will continue.

Hints for further verification

Even with `filter='data'`, *tarfile* is not suited for extracting untrusted files without prior inspection. Among other issues, the pre-defined filters do not prevent denial-of-service attacks. Users should do additional checks.

Here is an incomplete list of things to consider:

- Extract to a *new temporary directory* to prevent e.g. exploiting pre-existing links, and to make it easier to clean up after a failed extraction.
- Disallow symbolic links if you do not need the functionality.
- When working with untrusted data, use external (e.g. OS-level) limits on disk, memory and CPU usage.
- Check filenames against an allow-list of characters (to filter out control characters, confusables, foreign path separators, etc.).
- Check that filenames have expected extensions (discouraging files that execute when you "click on them", or extension-less files like Windows special device names).

- Limit the number of extracted files, total size of extracted data, filename length (including symlink length), and size of individual files.
- Check for files that would be shadowed on case-insensitive filesystems.

Also note that:

- Tar files may contain multiple versions of the same file. Later ones are expected to overwrite any earlier ones. This feature is crucial to allow updating tape archives, but can be abused maliciously.
- *tarfile* does not protect against issues with "live" data, e.g. an attacker tinkering with the destination (or source) directory while extraction (or archiving) is in progress.

Supporting older Python versions

Extraction filters were added to Python 3.12, but may be backported to older versions as security updates. To check whether the feature is available, use e.g. `hasattr(tarfile, 'data_filter')` rather than checking the Python version.

The following examples show how to support Python versions with and without the feature. Note that setting `extraction_filter` will affect any subsequent operations.

- Fully trusted archive:

```
my_tarfile.extraction_filter = (lambda member, path: member)
my_tarfile.extractall()
```

- Use the `'data'` filter if available, but revert to Python 3.11 behavior (`'fully_trusted'`) if this feature is not available:

```
my_tarfile.extraction_filter = getattr(tarfile, 'data_filter',
                                       (lambda member, path: member))
my_tarfile.extractall()
```

- Use the `'data'` filter; *fail* if it is not available:

```
my_tarfile.extractall(filter=tarfile.data_filter)
```

  or:

```
my_tarfile.extraction_filter = tarfile.data_filter
my_tarfile.extractall()
```

- Use the `'data'` filter; *warn* if it is not available:

```
if hasattr(tarfile, 'data_filter'):
    my_tarfile.extractall(filter='data')
else:
    # remove this when no longer needed
    warn_the_user('Extracting may be unsafe; consider updating Python')
    my_tarfile.extractall()
```

Stateful extraction filter example

While *tarfile*'s extraction methods take a simple *filter* callable, custom filters may be more complex objects with an internal state. It may be useful to write these as context managers, to be used like this:

```
with StatefulFilter() as filter_func:
    tar.extractall(path, filter=filter_func)
```

Such a filter can be written as, for example:

```
class StatefulFilter:
    def __init__(self):
        self.file_count = 0

    def __enter__(self):
        return self

    def __call__(self, member, path):
        self.file_count += 1
        return member

    def __exit__(self, *exc_info):
        print(f'{self.file_count} files extracted')
```

13.6.4 Command-Line Interface

Added in version 3.4.

The *tarfile* module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the *-c* option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar  spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the *-e* option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar  other-dir/
```

For a list of the files in a tar archive, use the *-l* option:

```
$ python -m tarfile -l monty.tar
```

Command-line options

-l <tarfile>

--list <tarfile>

List files in a tarfile.

-c <tarfile> <source1> ... <sourceN>

--create <tarfile> <source1> ... <sourceN>

Create tarfile from source files.

-e <tarfile> [<output_dir>]

--extract <tarfile> [<output_dir>]

Extract tarfile into the current directory if *output_dir* is not specified.

-t <tarfile>

--test <tarfile>

Test whether the tarfile is valid or not.

-v, --verbose

Verbose output.

--filter <filtername>

Specifies the *filter* for `--extract`. See *Extraction filters* for details. Only string names are accepted (that is, `fully_trusted`, `tar`, and `data`).

13.6.5 Examples

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall(filter='data')
tar.close()
```

How to extract a subset of a tar archive with *`TarFile.extractall()`* using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in size and is ", end="")
    if tarinfo.isreg():
        print("a regular file.")
    elif tarinfo.isdir():
        print("a directory.")
    else:
        print("something else.")
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in `TarFile.add()`:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

13.6.6 Supported tar formats

There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 ustar format (`USTAR_FORMAT`). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (`GNU_FORMAT`). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (`PAX_FORMAT`). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. Modern tar implementations, including GNU tar, bsdtar/libarchive and star, fully support extended *pax* features; some old or unmaintained libraries may not, but should treat *pax* archives as if they were in the universally supported *ustar* format. It is the current default format for new archives.

  It extends the existing *ustar* format with extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

13.6.7 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-*ASCII* characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The pax format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in `tarfile` are controlled by the *encoding* and *errors* keyword arguments of the `TarFile` class.

encoding defines the character encoding to use for the metadata in the archive. The default value is `sys.getfilesystemencoding()` or `'ascii'` as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section *Error Handlers*. The default scheme is `'surrogateescape'` which Python also uses for its file system calls, see *File Names, Command Line Arguments, and Environment Variables*.

For `PAX_FORMAT` archives (the default), *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

CHAPTER

FOURTEEN

FILE FORMATS

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages and are not related to e-mail.

14.1 csv — CSV File Reading and Writing

Source code: Lib/csv.py

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. CSV format was used for many years prior to attempts to describe the format in a standardized way in **RFC 4180**. The lack of a well-defined standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

The `csv` module implements classes to read and write tabular data in CSV format. It allows programmers to say, "write this data in the format preferred by Excel," or "read data from this file which was generated by Excel," without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

The `csv` module's `reader` and `writer` objects read and write sequences. Programmers can also read and write data in dictionary form using the `DictReader` and `DictWriter` classes.

See also

PEP 305 - CSV File API
The Python Enhancement Proposal which proposed this addition to Python.

14.1.1 Module Contents

The `csv` module defines the following functions:

`csv.reader`(*csvfile*, *dialect='excel'*, ***fmtparams*)

Return a *reader object* that will process lines from the given *csvfile*. A csvfile must be an iterable of strings, each in the reader's defined csv format. A csvfile is most commonly a file-like object or list. If *csvfile* is a file object, it should be opened with `newline=''`.[1] An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the `Dialect` class or one of the strings returned by the `list_dialects()` function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

[1] If `newline=''` is not specified, newlines embedded inside quoted fields will not be interpreted correctly, and on platforms that use `\r\n` linendings on write an extra `\r` will be added. It should always be safe to specify `newline=''`, since the csv module does its own (*universal*) newline handling.

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed unless the *QUOTE_NONNUMERIC* format option is specified (in which case unquoted fields are transformed into floats).

A short usage example:

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

csv.**writer**(*csvfile*, *dialect='excel'*, ***fmtparams*)

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. *csvfile* can be any object with a *write()* method. If *csvfile* is a file object, it should be opened with `newline=''`[Page 609, 1]. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the *list_dialects()* function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about dialects and formatting parameters, see the *Dialects and Formatting Parameters* section. To make it as easy as possible to interface with modules which implement the DB API, the value *None* is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. All other non-string data are stringified with *str()* before being written.

A short usage example:

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                            quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

csv.**register_dialect**(*name*[, *dialect*[, ***fmtparams*]])

Associate *dialect* with *name*. *name* must be a string. The dialect can be specified either by passing a sub-class of *Dialect*, or by *fmtparams* keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about dialects and formatting parameters, see section *Dialects and Formatting Parameters*.

csv.**unregister_dialect**(*name*)

Delete the dialect associated with *name* from the dialect registry. An *Error* is raised if *name* is not a registered dialect name.

csv.**get_dialect**(*name*)

Return the dialect associated with *name*. An *Error* is raised if *name* is not a registered dialect name. This function returns an immutable *Dialect*.

csv.**list_dialects**()

Return the names of all registered dialects.

csv.**field_size_limit**([*new_limit*])

Returns the current maximum field size allowed by the parser. If *new_limit* is given, this becomes the new limit.

The *csv* module defines the following classes:

class csv.**DictReader**(*f*, *fieldnames=None*, *restkey=None*, *restval=None*, *dialect='excel'*, **args*, ***kwds*)

Create an object that operates like a regular reader but maps the information in each row to a *dict* whose keys are given by the optional *fieldnames* parameter.

The *fieldnames* parameter is a *sequence*. If *fieldnames* is omitted, the values in the first row of file *f* will be used as the fieldnames and will be omitted from the results. If *fieldnames* is provided, they will be used and the first row will be included in the results. Regardless of how the fieldnames are determined, the dictionary preserves their original ordering.

If a row has more fields than fieldnames, the remaining data is put in a list and stored with the fieldname specified by *restkey* (which defaults to `None`). If a non-blank row has fewer fields than fieldnames, the missing values are filled-in with the value of *restval* (which defaults to `None`).

All other optional or keyword arguments are passed to the underlying *reader* instance.

If the argument passed to *fieldnames* is an iterator, it will be coerced to a *list*.

Changed in version 3.6: Returned rows are now of type `OrderedDict`.

Changed in version 3.8: Returned rows are now of type *dict*.

A short usage example:

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
{'first_name': 'John', 'last_name': 'Cleese'}
```

class csv.**DictWriter**(*f*, *fieldnames*, *restval=''*, *extrasaction='raise'*, *dialect='excel'*, **args*, ***kwds*)

Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a *sequence* of keys that identify the order in which values in the dictionary passed to the *writerow()* method are written to file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the *writerow()* method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to `'raise'`, the default value, a *ValueError* is raised. If it is set to `'ignore'`, extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying *writer* instance.

Note that unlike the *DictReader* class, the *fieldnames* parameter of the *DictWriter* class is not optional.

If the argument passed to *fieldnames* is an iterator, it will be coerced to a *list*.

A short usage example:

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})
```

class csv.**Dialect**

The *Dialect* class is a container class whose attributes contain information for how to handle doublequotes,

whitespace, delimiters, etc. Due to the lack of a strict CSV specification, different applications produce subtly different CSV data. *Dialect* instances define how *reader* and *writer* instances behave.

All available *Dialect* names are returned by *list_dialects()*, and they can be registered with specific *reader* and *writer* classes through their initializer (__init__) functions like this:

```
import csv

with open('students.csv', 'w', newline='') as csvfile:
    writer = csv.writer(csvfile, dialect='unix')
```

class csv.**excel**

The *excel* class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

class csv.**excel_tab**

The *excel_tab* class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

class csv.**unix_dialect**

The *unix_dialect* class defines the usual properties of a CSV file generated on UNIX systems, i.e. using '\n' as line terminator and quoting all fields. It is registered with the dialect name 'unix'.

Added in version 3.2.

class csv.**Sniffer**

The *Sniffer* class is used to deduce the format of a CSV file.

The *Sniffer* class provides two methods:

sniff(*sample*, *delimiters=None*)

Analyze the given *sample* and return a *Dialect* subclass reflecting the parameters found. If the optional *delimiters* parameter is given, it is interpreted as a string containing possible valid delimiter characters.

has_header(*sample*)

Analyze the sample text (presumed to be in CSV format) and return *True* if the first row appears to be a series of column headers. Inspecting each column, one of two key criteria will be considered to estimate if the sample contains a header:

- the second through n-th rows contain numeric values
- the second through n-th rows contain strings where at least one value's length differs from that of the putative header of that column.

Twenty rows after the first row are sampled; if more than half of columns + rows meet the criteria, *True* is returned.

> **Note**
>
> This method is a rough heuristic and may produce both false positives and negatives.

An example for *Sniffer* use:

```
with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...
```

The *csv* module defines the following constants:

csv.**QUOTE_ALL**

Instructs *writer* objects to quote all fields.

csv.**QUOTE_MINIMAL**

Instructs *writer* objects to only quote those fields which contain special characters such as *delimiter*, *quotechar* or any of the characters in *lineterminator*.

csv.**QUOTE_NONNUMERIC**

Instructs *writer* objects to quote all non-numeric fields.

Instructs *reader* objects to convert all non-quoted fields to type *float*.

> **Note**
>
> Some numeric types, such as *bool*, *Fraction*, or *IntEnum*, have a string representation that cannot be converted to *float*. They cannot be read in the *QUOTE_NONNUMERIC* and *QUOTE_STRINGS* modes.

csv.**QUOTE_NONE**

Instructs *writer* objects to never quote fields. When the current *delimiter* occurs in output data it is preceded by the current *escapechar* character. If *escapechar* is not set, the writer will raise *Error* if any characters that require escaping are encountered.

Instructs *reader* objects to perform no special processing of quote characters.

csv.**QUOTE_NOTNULL**

Instructs *writer* objects to quote all fields which are not `None`. This is similar to *QUOTE_ALL*, except that if a field value is `None` an empty (unquoted) string is written.

Instructs *reader* objects to interpret an empty (unquoted) field as `None` and to otherwise behave as *QUOTE_ALL*.

Added in version 3.12.

csv.**QUOTE_STRINGS**

Instructs *writer* objects to always place quotes around fields which are strings. This is similar to *QUOTE_NONNUMERIC*, except that if a field value is `None` an empty (unquoted) string is written.

Instructs *reader* objects to interpret an empty (unquoted) string as `None` and to otherwise behave as *QUOTE_NONNUMERIC*.

Added in version 3.12.

The *csv* module defines the following exception:

exception csv.**Error**

Raised by any of the functions when an error is detected.

14.1.2 Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the *Dialect* class containing various attributes describing the format of the CSV file. When creating *reader* or *writer* objects, the programmer can specify a string or a subclass of the *Dialect* class as the dialect parameter. In addition to, or instead of, the *dialect* parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the *Dialect* class.

Dialects support the following attributes:

Dialect.**delimiter**

A one-character string used to separate fields. It defaults to `','`.

Dialect.**doublequote**

Controls how instances of *quotechar* appearing inside a field should themselves be quoted. When *True*, the character is doubled. When *False*, the *escapechar* is used as a prefix to the *quotechar*. It defaults to *True*.

On output, if *doublequote* is *False* and no *escapechar* is set, *Error* is raised if a *quotechar* is found in a field.

Dialect.**escapechar**

A one-character string used by the writer to escape the *delimiter* if *quoting* is set to *QUOTE_NONE* and the *quotechar* if *doublequote* is *False*. On reading, the *escapechar* removes any special meaning from the following character. It defaults to *None*, which disables escaping.

Changed in version 3.11: An empty *escapechar* is not allowed.

Dialect.**lineterminator**

The string used to terminate lines produced by the *writer*. It defaults to `'\r\n'`.

> **Note**
>
> The *reader* is hard-coded to recognise either `'\r'` or `'\n'` as end-of-line, and ignores *lineterminator*. This behavior may change in the future.

Dialect.**quotechar**

A one-character string used to quote fields containing special characters, such as the *delimiter* or *quotechar*, or which contain new-line characters. It defaults to `'"'`.

Changed in version 3.11: An empty *quotechar* is not allowed.

Dialect.**quoting**

Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the *QUOTE_* constants* and defaults to *QUOTE_MINIMAL*.

Dialect.**skipinitialspace**

When *True*, spaces immediately following the *delimiter* are ignored. The default is *False*.

Dialect.**strict**

When `True`, raise exception *Error* on bad CSV input. The default is `False`.

14.1.3 Reader Objects

Reader objects (*DictReader* instances and objects returned by the *reader()* function) have the following public methods:

csvreader.**__next__**()

Return the next row of the reader's iterable object as a list (if the object was returned from *reader()*) or a dict (if it is a *DictReader* instance), parsed according to the current *Dialect*. Usually you should call this as `next(reader)`.

Reader objects have the following public attributes:

csvreader.**dialect**

A read-only description of the dialect in use by the parser.

csvreader.**line_num**

The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

DictReader objects have the following public attribute:

DictReader.**fieldnames**

If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

14.1.4 Writer Objects

writer objects (*DictWriter* instances and objects returned by the *writer()* function) have the following public methods. A *row* must be an iterable of strings or numbers for *writer* objects and a dictionary mapping fieldnames to strings or numbers (by passing them through *str()* first) for *DictWriter* objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

csvwriter.**writerow**(*row*)

Write the *row* parameter to the writer's file object, formatted according to the current *Dialect*. Return the return value of the call to the *write* method of the underlying file object.

Changed in version 3.5: Added support of arbitrary iterables.

csvwriter.**writerows**(*rows*)

Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

csvwriter.**dialect**

A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

DictWriter.**writeheader**()

Write a row with the field names (as specified in the constructor) to the writer's file object, formatted according to the current dialect. Return the return value of the *csvwriter.writerow()* call used internally.

Added in version 3.2.

Changed in version 3.8: *writeheader()* now also returns the value returned by the *csvwriter.writerow()* method it uses internally.

14.1.5 Examples

The simplest example of reading a CSV file:

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

Reading a file with an alternate format:

```
import csv
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

The corresponding simplest possible writing example is:

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Since *open()* is used to open a CSV file for reading, the file will by default be decoded into unicode using the system default encoding (see *locale.getencoding()*). To decode a file using a different encoding, use the `encoding` argument of open:

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

The same applies to writing in something other than the system default encoding: specify the encoding argument when opening the output file.

Registering a new dialect:

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print(row)
    except csv.Error as e:
        sys.exit('file {}, line {}: {}'.format(filename, reader.line_num, e))
```

And while the module doesn't directly support parsing strings, it can easily be done:

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

14.2 `configparser` — Configuration file parser

Source code: Lib/configparser.py

This module provides the *ConfigParser* class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

Note

This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

See also

Module *tomllib*
TOML is a well-specified format for application configuration files. It is specifically designed to be an improved version of INI.

Module *shlex*
: Support for creating Unix shell-like mini-languages which can also be used for application configuration files.

Module *json*
: The `json` module implements a subset of JavaScript syntax which is sometimes used for configuration, but does not support comments.

14.2.1 Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[forge.example]
User = hg

[topsecret.server.example]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described *in the following section*. Essentially, the file consists of sections, each of which contains keys with values. *configparser* classes can read and write such files. Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                      'Compression': 'yes',
...                      'CompressionLevel': '9'}
>>> config['forge.example'] = {}
>>> config['forge.example']['User'] = 'hg'
>>> config['topsecret.server.example'] = {}
>>> topsecret = config['topsecret.server.example']
>>> topsecret['Port'] = '50022'     # mutates the parser
>>> topsecret['ForwardX11'] = 'no'  # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...   config.write(configfile)
...
```

As you can see, we can treat a config parser much like a dictionary. There are differences, *outlined later*, but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['forge.example', 'topsecret.server.example']
>>> 'forge.example' in config
```

(continues on next page)

(continued from previous page)

```
True
>>> 'python.org' in config
False
>>> config['forge.example']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.example']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['forge.example']:
...     print(key)
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['forge.example']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which provides default values for all other sections[1]. Note also that keys in sections are case-insensitive and stored in lowercase[1].

It is possible to read several configurations into a single *`ConfigParser`*, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the previously existing keys are retained. The example below reads in an `override.ini` file, which will override any conflicting keys from the `example.ini` file.

```
[DEFAULT]
ServerAliveInterval = -1
```

```
>>> config_override = configparser.ConfigParser()
>>> config_override['DEFAULT'] = {'ServerAliveInterval': '-1'}
>>> with open('override.ini', 'w') as configfile:
...     config_override.write(configfile)
...
>>> config_override = configparser.ConfigParser()
>>> config_override.read(['example.ini', 'override.ini'])
['example.ini', 'override.ini']
>>> print(config_override.get('DEFAULT', 'ServerAliveInterval'))
-1
```

This behaviour is equivalent to a *`ConfigParser.read()`* call with several files passed to the *filenames* parameter.

14.2.2 Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
```

(continues on next page)

[1] Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the *Customizing Parser Behaviour* section.

(continued from previous page)

```
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`. This is why config parsers also provide *getboolean()*. This method is case-insensitive and recognizes Boolean values from `'yes'`/`'no'`, `'on'`/`'off'`, `'true'`/`'false'` and `'1'`/`'0'`[Page 618, 1]. For example:

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['forge.example'].getboolean('ForwardX11')
True
>>> config.getboolean('forge.example', 'Compression')
True
```

Apart from *getboolean()*, config parsers also provide equivalent *getint()* and *getfloat()* methods. You can register your own converters and customize the provided ones.[Page 618, 1]

14.2.3 Fallback Values

As with a dictionary, you can use a section's *get()* method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the `'CompressionLevel'` key was specified only in the `'DEFAULT'` section. If we try to get it from the section `'topsecret.server.example'`, we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level *get()* method provides a custom, more complex interface, maintained for backwards compatibility. When using this method, a fallback value can be provided via the `fallback` keyword-only argument:

```
>>> config.get('forge.example', 'monster',
...            fallback='No such things as monsters')
'No such things as monsters'
```

The same `fallback` argument can be used with the *getint()*, *getfloat()* and *getboolean()* methods, for example:

```
>>> 'BatchMode' in topsecret
False
>>> topsecret.getboolean('BatchMode', fallback=True)
True
>>> config['DEFAULT']['BatchMode'] = 'no'
>>> topsecret.getboolean('BatchMode', fallback=True)
False
```

14.2.4 Supported INI File Structure

A configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (= or : by default[Page 618, 1]). By default, section names are case sensitive but keys are not[Page 618, 1]. Leading and trailing whitespace is removed from keys and values. Values can be omitted if the parser is configured to allow it[Page 618, 1], in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

By default, a valid section name can be any string that does not contain '\n'. To change this, see *ConfigParser.SECTCRE*.

The first section name may be omitted if the parser is configured to allow an unnamed top level section with `allow_unnamed_section=True`. In this case, the keys/values may be retrieved by *UNNAMED_SECTION* as in `config[UNNAMED_SECTION]`.

Configuration files may include comments, prefixed by specific characters (`#` and `;` by default[Page 618, 1]). Comments may appear on their own on an otherwise empty line, possibly indented.[Page 618, 1]

For example:

```
[Simple Values]
key=value
spaces in keys=allowed
spaces in values=allowed as well
spaces around the delimiter = obviously
you can also use : to delimit keys from values

[All Values Are Strings]
values like this: 1000000
or this: 3.14159265359
are they treated as numbers? : no
integers, floats and booleans are held as: strings
can use the API to get converted values directly: true

[Multiline Values]
chorus: I'm a lumberjack, and I'm okay
    I sleep all night and I work all day

[No Values]
key_without_value
empty string value here =

[You can use comments]
# like this
; or this

# By default only in an empty line.
# Inline comments can be harmful because they prevent users
# from using the delimiting characters as parts of values.
# That being said, this can be customized.

    [Sections Can Be Indented]
        can_values_be_as_well = True
        does_that_mean_anything_special = False
        purpose = formatting for readability
        multiline_values = are
            handled just fine as
            long as they are indented
            deeper than the first line
```

(continues on next page)

(continued from previous page)

```
            of a value
        # Did I mention we can indent comments, too?
```

14.2.5 Unnamed Sections

The name of the first section (or unique) may be omitted and values retrieved by the *UNNAMED_SECTION* attribute.

```
>>> config = """
... option = value
...
... [  Section 2  ]
... another = val
... """
>>> unnamed = configparser.ConfigParser(allow_unnamed_section=True)
>>> unnamed.read_string(config)
>>> unnamed.get(configparser.UNNAMED_SECTION, 'option')
'value'
```

14.2.6 Interpolation of values

On top of the core functionality, *ConfigParser* supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

class configparser.**BasicInterpolation**

The default implementation used by *ConfigParser*. It enables values to contain format strings which refer to other values in the same section, or values in the special default section[Page 618, 1]. Additional default values can be provided on initialization.

For example:

```
[Paths]
home_dir: /Users
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures

[Escape]
# use a %% to escape the % sign (% is the only character that needs to be␣
↪escaped):
gain: 80%%
```

In the example above, *ConfigParser* with *interpolation* set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir` (`/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With `interpolation` set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

class configparser.**ExtendedInterpolation**

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures

[Escape]
# use a $$ to escape the $ sign ($ is the only character that needs to be␣
↪escaped):
cost: $$80
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local

[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/

[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
python_dir: ${Frameworks:path}/Python/Versions/${Frameworks:Python}
```

14.2.7 Mapping Protocol Access

Added in version 3.2.

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of *configparser*, the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

configparser objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the *MutableMapping* ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner[Page 618, 1]. E.g. `for option in parser["section"]` yields only `optionxform`'ed option key names. This means lowercased keys by default. At the same time, for a section that holds the key `'a'`, both expressions return `True`:

```
"a" in parser["section"]
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a *KeyError*.
- `DEFAULTSECT` cannot be removed from the parser:
  - trying to delete it raises *ValueError*,
  - `parser.clear()` leaves it intact,

  - `parser.popitem()` never returns it.

- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic configparser API.
- `parser.items()` is compatible with the mapping protocol (returns a list of *section_name*, *section_proxy* pairs including the DEFAULTSECT). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of *option*, *value* pairs for a specified `section`, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

14.2.8 Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. *configparser* goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

  This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

  Hint: if you want to specify default values for a specific section, use *read_dict()* before you read the actual file.

- *dict_type*, default value: *dict*

  This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the standard dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

  An alternative dictionary type can be used for example to sort sections and options on write-back.

  Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys will be ordered. For example:

```
>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                                'key2': 'value2',
...                                'key3': 'value3'},
...                   'section2': {'keyA': 'valueA',
...                                'keyB': 'valueB',
...                                'keyC': 'valueC'},
...                   'section3': {'foo': 'x',
...                                'bar': 'y',
...                                'baz': 'z'}
... })
>>> parser.sections()
['section1', 'section2', 'section3']
>>> [option for option in parser['section3']]
['foo', 'bar', 'baz']
```

- *allow_no_value*, default value: `False`

  Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by *configparser*. The *allow_no_value* parameter to the constructor can be used to indicate that such values should be accepted:

```
>>> import configparser

>>> sample_config = """
... [mysqld]
...   user = mysql
...   pid-file = /var/run/mysqld/mysqld.pid
...   skip-external-locking
...   old_passwords = 1
...   skip-bdb
...   # we don't need ACID today
...   skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_value=True)
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise an error:
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
  ...
KeyError: 'does-not-exist'
```

- *delimiters*, default value: `('=', ':')`

  Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

  See also the *space_around_delimiters* argument to *ConfigParser.write()*.

- *comment_prefixes*, default value: `('#', ';')`

- *inline_comment_prefixes*, default value: `None`

  Comment prefixes are strings that indicate the start of a valid comment within a config file. *comment_prefixes* are used only on otherwise empty lines (optionally indented) whereas *inline_comment_prefixes* can be used after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and `'#'` and `';'` are used as prefixes for whole line comments.

  Changed in version 3.2: In previous versions of *configparser* behaviour matched `comment_prefixes=('#',';')` and `inline_comment_prefixes=(';',)`.

  Please note that config parsers don't support escaping of comment prefixes so using *inline_comment_prefixes* may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting *inline_comment_prefixes*. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```
>>> from configparser import ConfigParser, ExtendedInterpolation
>>> parser = ConfigParser(interpolation=ExtendedInterpolation())
>>> # the default BasicInterpolation could be used as well
>>> parser.read_string("""
... [DEFAULT]
... hash = #
...
... [hashes]
```

(continues on next page)

(continued from previous page)

```
... shebang =
...   ${hash}!/usr/bin/env python
...   ${hash} -*- coding: utf-8 -*-
...
... extensions =
...   enabled_extension
...   another_extension
...   #disabled_by_comment
...   yet_another_extension
...
... interpolation not necessary = if # is not at line start
... even in multiline values = line #1
...   line #2
...   line #3
... """)
>>> print(parser['hashes']['shebang'])

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])

enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not necessary'])
if # is not at line start
>>> print(parser['hashes']['even in multiline values'])
line #1
line #2
line #3
```

- *strict*, default value: `True`

  When set to `True`, the parser will not allow for any section or option duplicates while reading from a single source (using *read_file()*, *read_string()* or *read_dict()*). It is recommended to use strict parsers in new applications.

  Changed in version 3.2: In previous versions of *configparser* behaviour matched `strict=False`.

- *empty_lines_in_values*, default value: `True`

  In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```
[Section]
key = multiline
  value with a gotcha

 this = is still a part of the multiline value of 'key'
```

  This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- *default_section*, default value: `configparser.DEFAULTSECT` (that is: `"DEFAULT"`)

  The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is

normally called "DEFAULT" but this can be customized to point to any other valid section name. Some typical values include: "general" or "common". The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the parser_instance.default_section attribute and may be modified at runtime (i.e. to convert files from one format to another).

- *interpolation*, default value: configparser.BasicInterpolation

  Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. None can be used to turn off interpolation completely, ExtendedInterpolation() provides a more advanced variant inspired by zc.buildout. More on the subject in the *dedicated documentation section*. *RawConfigParser* has a default value of None.

- *converters*, default value: not set

  Config parsers provide option value getters that perform type conversion. By default *getint()*, *getfloat()*, and *getboolean()* are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing {'decimal': decimal.Decimal} would add getdecimal() on both the parser object and all section proxies. In other words, it will be possible to write both parser_instance.getdecimal('section', 'key', fallback=0) and parser_instance['section'].getdecimal('key', 0).

  If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with get, it will be available on all section proxies, in the dict-compatible form (see the getdecimal() example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

ConfigParser.**BOOLEAN_STATES**

By default when using *getboolean()*, config parsers consider the following values True: '1', 'yes', 'true', 'on' and the following values False: '0', 'no', 'false', 'off'. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```
>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope': False}
>>> custom['section1'].getboolean('funky')
False
```

Other typical Boolean pairs include accept/reject or enabled/disabled.

ConfigParser.**optionxform**(*option*)

This method transforms option names on every read, get, or set operation. The default converts the name to lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```
>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
```

(continues on next page)

(continued from previous page)

```
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())
['AnotherKey']
```

Note

The optionxform function transforms option names to a canonical form. This should be an idempotent function: if the name is already in canonical form, it should be returned unchanged.

`ConfigParser.SECTCRE`

A compiled regular expression used to parse section headers. The default matches `[section]` to the name `"section"`. Whitespace is considered part of the section name, thus `[ larch ]` will be read as a section of name `" larch "`. Override this attribute if that's unsuitable. For example:

```
>>> import re
>>> config = """
... [Section 1]
... option = value
...
... [  Section 2  ]
... another = val
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', '  Section 2  ']
>>> custom = configparser.ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^]]+?) *\]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']
```

Note

While ConfigParser objects also use an `OPTCRE` attribute for recognizing option lines, it's not recommended to override it because that would interfere with constructor options *allow_no_value* and *delimiters*.

14.2.9 Legacy API Examples

Mainly because of backwards compatibility concerns, *configparser* provides also a legacy API with explicit `get`/`set` methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```
import configparser

config = configparser.RawConfigParser()

# Please note that using RawConfigParser's set functions, you can assign
# non-string values to keys internally, but will receive an error when
# attempting to write to a file or when you get it in non-raw mode. Setting
# values using the mapping protocol or ConfigParser's set() does not allow
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))
```

To get interpolation, use *ConfigParser*:

```
import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you wish to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False))  # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))   # -> "%(bar)s is %(baz)s!"

# The optional *vars* argument is a dict with members that will take
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation',
                                       'baz': 'evil'}))

# The optional *fallback* argument can be used to provide a fallback value
```

(continues on next page)

(continued from previous page)

```
print(cfg.get('Section1', 'foo'))
      # -> "Python is fun!"

print(cfg.get('Section1', 'foo', fallback='Monty is not.'))
      # -> "Python is fun!"

print(cfg.get('Section1', 'monster', fallback='No such things as monsters.'))
      # -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise NoOptionError
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
      # -> None
```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```
import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))      # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))      # -> "Life is hard!"
```

14.2.10 ConfigParser Objects

class configparser.**ConfigParser**(*defaults=None*, *dict_type=dict*, *allow_no_value=False*, ***, *delimiters=('=', ':')*, *comment_prefixes=('#', ';')*, *inline_comment_prefixes=None*, *strict=True*, *empty_lines_in_values=True*, *default_section=configparser.DEFAULTSECT*, *interpolation=BasicInterpolation()*, *converters={}*, *allow_unnamed_section=False*)

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment_prefixes* is given, it will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline_comment_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is `True` (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising *DuplicateSectionError* or *DuplicateOptionError*. When *empty_lines_in_values* is `False` (default: `True`), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow_no_value* is `True` (default: `False`), options without values are accepted; the value held for these is `None` and they are serialized without the trailing delimiter.

When *default_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named `"DEFAULT"`). This value can be retrieved and changed at runtime using the `default_section` instance attribute. This won't re-evaluate an already parsed config file, but will be used when writing parsed settings to a new config file.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the *dedicated documentation section*.

All option names used in interpolation will be passed through the *optionxform()* method just like any other option name reference. For example, using the default implementation of *optionxform()* (which converts option names to lower case), the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

When *converters* is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding `get*()` method on the parser object and section proxies.

When *allow_unnamed_section* is `True` (default: `False`), the first section name can be omitted. See the *"Unnamed Sections" section*.

It is possible to read several configurations into a single *ConfigParser*, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the previously existing keys are retained. The example below reads in an `override.ini` file, which will override any conflicting keys from the `example.ini` file.

```
[DEFAULT]
ServerAliveInterval = -1
```

```
>>> config_override = configparser.ConfigParser()
>>> config_override['DEFAULT'] = {'ServerAliveInterval': '-1'}
>>> with open('override.ini', 'w') as configfile:
...     config_override.write(configfile)
...
>>> config_override = configparser.ConfigParser()
>>> config_override.read(['example.ini', 'override.ini'])
['example.ini', 'override.ini']
>>> print(config_override.get('DEFAULT', 'ServerAliveInterval'))
-1
```

Changed in version 3.1: The default *dict_type* is *collections.OrderedDict*.

Changed in version 3.2: *allow_no_value*, *delimiters*, *comment_prefixes*, *strict*, *empty_lines_in_values*, *default_section* and *interpolation* were added.

Changed in version 3.5: The *converters* argument was added.

Changed in version 3.7: The *defaults* argument is read with *read_dict()*, providing consistent behavior across the parser: non-string keys and values are implicitly converted to strings.

Changed in version 3.8: The default *dict_type* is *dict*, since it now preserves insertion order.

Changed in version 3.13: Raise a *MultilineContinuationError* when *allow_no_value* is `True`, and a key without a value is continued with an indented line.

Changed in version 3.13: The *allow_unnamed_section* argument was added.

defaults()

Return a dictionary containing the instance-wide defaults.

sections()

Return a list of the sections available; the *default section* is not included in the list.

add_section(*section*)

Add a section named *section* to the instance. If a section by the given name already exists, *DuplicateSectionError* is raised. If the *default section* name is passed, *ValueError* is raised. The name of the section must be a string; if not, *TypeError* is raised.

Changed in version 3.2: Non-string section names raise *TypeError*.

has_section(*section*)

Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

options(*section*)

Return a list of options available in the specified *section*.

has_option(*section*, *option*)

If the given *section* exists, and contains the given *option*, return `True`; otherwise return `False`. If the specified *section* is `None` or an empty string, DEFAULT is assumed.

read(*filenames*, *encoding=None*)

Attempt to read and parse an iterable of filenames, returning a list of filenames which were successfully parsed.

If *filenames* is a string, a `bytes` object or a *path-like object*, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify an iterable of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the iterable will be read.

If none of the named files exist, the `ConfigParser` instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using `read_file()` before calling `read()` for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')],
            encoding='cp1250')
```

Changed in version 3.2: Added the *encoding* parameter. Previously, all files were read using the default encoding for `open()`.

Changed in version 3.6.1: The *filenames* parameter accepts a *path-like object*.

Changed in version 3.7: The *filenames* parameter accepts a `bytes` object.

read_file(*f*, *source=None*)

Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a `name` attribute, that is used for *source*; the default is `'<???>'`.

Added in version 3.2: Replaces `readfp()`.

read_string(*string*, *source='<string>'*)

Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, `'<string>'` is used. This should commonly be a filesystem path or a URL.

Added in version 3.2.

read_dict(*dictionary*, *source='<dict>'*)

Load configuration from any object that provides a dict-like `items()` method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, `<dict>` is used.

This method can be used to copy state between parsers.

Added in version 3.2.

get(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *DEFAULTSECT* in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. `None` can be provided as a *fallback* value.

All the `'%'` interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

Changed in version 3.2: Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

getint(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to an integer. See *get()* for explanation of *raw*, *vars* and *fallback*.

getfloat(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a floating-point number. See *get()* for explanation of *raw*, *vars* and *fallback*.

getboolean(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are `'1'`, `'yes'`, `'true'`, and `'on'`, which cause this method to return `True`, and `'0'`, `'no'`, `'false'`, and `'off'`, which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise *ValueError*. See *get()* for explanation of *raw*, *vars* and *fallback*.

items(*raw=False*, *vars=None*)

items(*section*, *raw=False*, *vars=None*)

When *section* is not given, return a list of *section_name*, *section_proxy* pairs, including DEFAULTSECT.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the *get()* method.

Changed in version 3.8: Items present in *vars* no longer appear in the result. The previous behaviour mixed actual parser options with variables provided for interpolation.

set(*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise *NoSectionError*. *option* and *value* must be strings; if not, *TypeError* is raised.

write(*fileobject*, *space_around_delimiters=True*)

Write a representation of the configuration to the specified *file object*, which must be opened in text mode (accepting strings). This representation can be parsed by a future *read()* call. If *space_around_delimiters* is true, delimiters between keys and values are surrounded by spaces.

Note

Comments in the original configuration file are not preserved when writing the configuration back. What is considered a comment, depends on the given values for *comment_prefix* and *inline_comment_prefix*.

remove_option(*section*, *option*)

Remove the specified *option* from the specified *section*. If the section does not exist, raise *NoSectionError*. If the option existed to be removed, return *True*; otherwise return *False*.

remove_section(*section*)

Remove the specified *section* from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

optionxform(*option*)

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before *optionxform()* is called.

configparser.**UNNAMED_SECTION**

A special object representing a section name used to reference the unnamed section (see *Unnamed Sections*).

configparser.**MAX_INTERPOLATION_DEPTH**

The maximum depth for recursive interpolation for *get()* when the *raw* parameter is false. This is relevant only when the default *interpolation* is used.

14.2.11 RawConfigParser Objects

class configparser.**RawConfigParser**(*defaults=None*, *dict_type=dict*, *allow_no_value=False*, ***, *delimiters=('=', ':')*, *comment_prefixes=('#', ';')*, *inline_comment_prefixes=None*, *strict=True*, *empty_lines_in_values=True*, *default_section=configparser.DEFAULTSECT*, *interpolation=BasicInterpolation()*, *converters={}*, *allow_unnamed_section=False*)

Legacy variant of the *ConfigParser*. It has interpolation disabled by default and allows for non-string section names, option names, and values via its unsafe `add_section` and `set` methods, as well as the legacy `defaults=` keyword argument handling.

Changed in version 3.2: *allow_no_value*, *delimiters*, *comment_prefixes*, *strict*, *empty_lines_in_values*, *default_section* and *interpolation* were added.

Changed in version 3.5: The *converters* argument was added.

Changed in version 3.8: The default *dict_type* is *dict*, since it now preserves insertion order.

Changed in version 3.13: The *allow_unnamed_section* argument was added.

> **Note**
>
> Consider using *ConfigParser* instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

add_section(*section*)

Add a section named *section* to the instance. If a section by the given name already exists, *DuplicateSectionError* is raised. If the *default section* name is passed, *ValueError* is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

set(*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise *NoSectionError*. While it is possible to use *RawConfigParser* (or *ConfigParser* with *raw* parameters set to true) for

internal storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

14.2.12 Exceptions

exception configparser.**Error**

Base class for all other *configparser* exceptions.

exception configparser.**NoSectionError**

Exception raised when a specified section is not found.

exception configparser.**DuplicateSectionError**

Exception raised if *add_section()* is called with the name of a section that is already present or in strict parsers when a section if found more than once in a single input file, string or dictionary.

Changed in version 3.2: Added the optional *source* and *lineno* attributes and parameters to `__init__()`.

exception configparser.**DuplicateOptionError**

Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

exception configparser.**NoOptionError**

Exception raised when a specified option is not found in the specified section.

exception configparser.**InterpolationError**

Base class for exceptions raised when problems occur performing string interpolation.

exception configparser.**InterpolationDepthError**

Exception raised when string interpolation cannot be completed because the number of iterations exceeds *MAX_INTERPOLATION_DEPTH*. Subclass of *InterpolationError*.

exception configparser.**InterpolationMissingOptionError**

Exception raised when an option referenced from a value does not exist. Subclass of *InterpolationError*.

exception configparser.**InterpolationSyntaxError**

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of *InterpolationError*.

exception configparser.**MissingSectionHeaderError**

Exception raised when attempting to parse a file which has no section headers.

exception configparser.**ParsingError**

Exception raised when errors occur attempting to parse a file.

Changed in version 3.12: The `filename` attribute and `__init__()` constructor argument were removed. They have been available using the name `source` since 3.2.

exception configparser.**MultilineContinuationError**

Exception raised when a key without a corresponding value is continued with an indented line.

Added in version 3.13.

14.3 tomllib — Parse TOML files

Added in version 3.11.

Source code: Lib/tomllib

This module provides an interface for parsing TOML 1.0.0 (Tom's Obvious Minimal Language, https://toml.io). This module does not support writing TOML.

See also

The Tomli-W package is a TOML writer that can be used in conjunction with this module, providing a write API familiar to users of the standard library `marshal` and `pickle` modules.

See also

The TOML Kit package is a style-preserving TOML library with both read and write capability. It is a recommended replacement for this module for editing already existing TOML files.

This module defines the following functions:

`tomllib.`**`load`**(*fp*, */*, ***, *parse_float=float*)

Read a TOML file. The first argument should be a readable and binary file object. Return a `dict`. Convert TOML types to Python using this *conversion table*.

parse_float will be called with the string of every TOML float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for TOML floats (e.g. `decimal.Decimal`). The callable must not return a `dict` or a `list`, else a `ValueError` is raised.

A `TOMLDecodeError` will be raised on an invalid TOML document.

`tomllib.`**`loads`**(*s*, */*, ***, *parse_float=float*)

Load TOML from a `str` object. Return a `dict`. Convert TOML types to Python using this *conversion table*. The *parse_float* argument has the same meaning as in `load()`.

A `TOMLDecodeError` will be raised on an invalid TOML document.

The following exceptions are available:

`exception` `tomllib.`**`TOMLDecodeError`**

Subclass of `ValueError`.

14.3.1 Examples

Parsing a TOML file:

```
import tomllib

with open("pyproject.toml", "rb") as f:
    data = tomllib.load(f)
```

Parsing a TOML string:

```
import tomllib

toml_str = """
python-version = "3.11.0"
python-implementation = "CPython"
"""

data = tomllib.loads(toml_str)
```

14.3.2 Conversion Table

TOML	Python
TOML document	dict
string	str
integer	int
float	float (configurable with *parse_float*)
boolean	bool
offset date-time	datetime.datetime (`tzinfo` attribute set to an instance of `datetime.timezone`)
local date-time	datetime.datetime (`tzinfo` attribute set to `None`)
local date	datetime.date
local time	datetime.time
array	list
table	dict
inline table	dict
array of tables	list of dicts

14.4 `netrc` — netrc file processing

Source code: Lib/netrc.py

The *netrc* class parses and encapsulates the netrc file format used by the Unix **ftp** program and other FTP clients.

class netrc.**netrc**([*file*])

A *netrc* instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file `.netrc` in the user's home directory – as determined by *os.path.expanduser()* – will be read. Otherwise, a *FileNotFoundError* exception will be raised. Parse errors will raise *NetrcParseError* with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the `.netrc` file will raise a *NetrcParseError* if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of ftp and other programs that use `.netrc`.

Changed in version 3.4: Added the POSIX permission check.

Changed in version 3.7: *os.path.expanduser()* is used to find the location of the `.netrc` file when *file* is not passed as argument.

Changed in version 3.10: *netrc* try UTF-8 encoding before using locale specific encoding. The entry in the netrc file no longer needs to contain all tokens. The missing tokens' value default to an empty string. All the tokens and their values now can contain arbitrary characters, like whitespace and non-ASCII characters. If the login name is anonymous, it won't trigger the security check.

exception netrc.**NetrcParseError**

Exception raised by the *netrc* class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes:

msg

Textual explanation of the error.

filename

The name of the source file.

lineno

The line number on which the error was found.

14.4.1 netrc Objects

A *netrc* instance has the following methods:

netrc.**authenticators**(*host*)

Return a 3-tuple `(login, account, password)` of authenticators for *host*. If the netrc file did not contain an entry for the given host, return the tuple associated with the 'default' entry. If neither matching host nor default entry is available, return `None`.

netrc.**__repr__**()

Dump the class data as a string in the format of a netrc file. (This discards comments and may reorder the entries.)

Instances of *netrc* have public instance variables:

netrc.**hosts**

Dictionary mapping host names to `(login, account, password)` tuples. The 'default' entry, if any, is represented as a pseudo-host by that name.

netrc.**macros**

Dictionary mapping macro names to string lists.

14.5 plistlib — Generate and parse Apple .plist files

Source code: Lib/plistlib.py

This module provides an interface for reading and writing the "property list" files used by Apple, primarily on macOS and iOS. This module supports both binary and XML plist files.

The property list (`.plist`) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the *dump()* and *load()* functions.

To work with plist data in bytes or string objects, use *dumps()* and *loads()*.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), *bytes*, *bytearray* or *datetime.datetime* objects.

Changed in version 3.4: New API, old API deprecated. Support for binary format plists added.

Changed in version 3.8: Support added for reading and writing *UID* tokens in binary plists as used by NSKeyedArchiver and NSKeyedUnarchiver.

Changed in version 3.9: Old API removed.

See also

PList manual page
Apple's documentation of the file format.

This module defines the following functions:

plistlib.**load**(*fp*, *, *fmt=None*, *dict_type=dict*, *aware_datetime=False*)

Read a plist file. *fp* should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The *fmt* is the format of the file and the following values are valid:

- *None*: Autodetect the file format
- *FMT_XML*: XML file format

- *FMT_BINARY*: Binary plist format

The *dict_type* is the type used for dictionaries that are read from the plist file.

When *aware_datetime* is true, fields with type `datetime.datetime` will be created as *aware object*, with `tzinfo` as *datetime.UTC*.

XML data for the *FMT_XML* format is parsed using the Expat parser from *xml.parsers.expat* – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser raises *InvalidFileException* when the file cannot be parsed.

Added in version 3.4.

Changed in version 3.13: The keyword-only parameter *aware_datetime* has been added.

plistlib.**loads**(*data*, *, *fmt=None*, *dict_type=dict*, *aware_datetime=False*)

Load a plist from a bytes or string object. See *load()* for an explanation of the keyword arguments.

Added in version 3.4.

Changed in version 3.13: *data* can be a string when *fmt* equals *FMT_XML*.

plistlib.**dump**(*value*, *fp*, *, *fmt=FMT_XML*, *sort_keys=True*, *skipkeys=False*, *aware_datetime=False*)

Write *value* to a plist file. *fp* should be a writable, binary file object.

The *fmt* argument specifies the format of the plist file and can be one of the following values:

- *FMT_XML*: XML formatted plist file
- *FMT_BINARY*: Binary formatted plist file

When *sort_keys* is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When *skipkeys* is false (the default) the function raises *TypeError* when a key of a dictionary is not a string, otherwise such keys are skipped.

When *aware_datetime* is true and any field with type `datetime.datetime` is set as an *aware object*, it will convert to UTC timezone before writing it.

A *TypeError* will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An *OverflowError* will be raised for integer values that cannot be represented in (binary) plist files.

Added in version 3.4.

Changed in version 3.13: The keyword-only parameter *aware_datetime* has been added.

plistlib.**dumps**(*value*, *, *fmt=FMT_XML*, *sort_keys=True*, *skipkeys=False*, *aware_datetime=False*)

Return *value* as a plist-formatted bytes object. See the documentation for *dump()* for an explanation of the keyword arguments of this function.

Added in version 3.4.

The following classes are available:

class plistlib.**UID**(*data*)

Wraps an *int*. This is used when reading or writing NSKeyedArchiver encoded data, which contains UID (see PList manual).

data

Int value of the UID. It must be in the range `0 <= data < 2**64`.

Added in version 3.8.

The following constants are available:

plistlib.**FMT_XML**

The XML format for plist files.

Added in version 3.4.

plistlib.**FMT_BINARY**

The binary format for plist files

Added in version 3.4.

The module defines the following exceptions:

exception plistlib.**InvalidFileException**

Raised when a file cannot be parsed.

Added in version 3.4.

14.5.1 Examples

Generating a plist:

```
import datetime
import plistlib

pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\xe4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.now()
)
print(plistlib.dumps(pl).decode())
```

Parsing a plist:

```
import plistlib

plist = b"""<plist version="1.0">
<dict>
    <key>foo</key>
    <string>bar</string>
</dict>
</plist>"""
pl = plistlib.loads(plist)
print(pl["foo"])
```

CHAPTER

FIFTEEN

CRYPTOGRAPHIC SERVICES

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. Here's an overview:

15.1 `hashlib` — Secure hashes and message digests

Source code: Lib/hashlib.py

This module implements a common interface to many different hash algorithms. Included are the FIPS secure hash algorithms SHA224, SHA256, SHA384, SHA512, (defined in the FIPS 180-4 standard), the SHA-3 series (defined in the FIPS 202 standard) as well as the legacy algorithms SHA1 (formerly part of FIPS) and the MD5 algorithm (defined in internet **RFC 1321**).

> **Note**
>
> If you want the adler32 or crc32 hash functions, they are available in the `zlib` module.

15.1.1 Hash algorithms

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha256()` to create a SHA-256 hash object. You can now feed this object with *bytes-like objects* (normally `bytes`) using the `update` method. At any point you can ask it for the *digest* of the concatenation of the data fed to it so far using the `digest()` or `hexdigest()` methods.

To allow multithreading, the Python *GIL* is released while computing a hash supplied more than 2047 bytes of data at once in its constructor or `.update` method.

Constructors for hash algorithms that are always present in this module are `sha1()`, `sha224()`, `sha256()`, `sha384()`, `sha512()`, `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()`, `blake2b()`, and `blake2s()`. `md5()` is normally available as well, though it may be missing or blocked if you are using a rare "FIPS compliant" build of Python. These correspond to `algorithms_guaranteed`.

Additional algorithms may also be available if your Python distribution's `hashlib` was linked against a build of OpenSSL that provides others. Others *are not guaranteed available* on all installations and will only be accessible by name via `new()`. See `algorithms_available`.

> **Warning**
>
> Some algorithms have known hash collision weaknesses (including MD5 and SHA1). Refer to Attacks on cryptographic hash algorithms and the *hashlib-seealso* section at the end of this document.

Added in version 3.6: SHA3 (Keccak) and SHAKE constructors `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()` were added. `blake2b()` and `blake2s()` were added. Changed in version 3.9: All hashlib constructors take a keyword-only argument *usedforsecurity* with default value `True`. A false

value allows the use of insecure and blocked hashing algorithms in restricted environments. `False` indicates that the hashing algorithm is not used in a security context, e.g. as a non-cryptographic one-way compression function.

Changed in version 3.9: Hashlib now uses SHA3 and SHAKE from OpenSSL if it provides it.

Changed in version 3.12: For any of the MD5, SHA1, SHA2, or SHA3 algorithms that the linked OpenSSL does not provide we fall back to a verified implementation from the HACL* project.

15.1.2 Usage

To obtain the digest of the byte string `b"Nobody inspects the spammish repetition"`:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xdd}Ae\x15\x93\xc5\xfe\\\x00o\xa5u+7\xfd\xdf\xf7\xbcN\x84:\xa6\xaf\x0c\
↪x95\x0fK\x94\x06'
>>> m.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

More condensed:

```
>>> hashlib.sha256(b"Nobody inspects the spammish repetition").hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

15.1.3 Constructors

hashlib.**new**(*name*, [*data*,]*, *usedforsecurity=True*)

Is a generic constructor that takes the string *name* of the desired algorithm as its first parameter. It also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer.

Using *new()* with an algorithm name:

```
>>> h = hashlib.new('sha256')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

hashlib.**md5**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha1**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha224**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha256**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha384**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha512**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_224**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_256**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_384**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_512**([*data*,]*, *usedforsecurity=True*)

Named constructors such as these are faster than passing an algorithm name to *new()*.

15.1.4 Attributes

Hashlib provides the following constant module attributes:

hashlib.**algorithms_guaranteed**

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms. Note that 'md5' is in this list despite some upstream vendors offering an odd "FIPS compliant" Python build that excludes it.

Added in version 3.2.

hashlib.**algorithms_available**

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to *new()*. *algorithms_guaranteed* will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

Added in version 3.2.

15.1.5 Hash Objects

The following values are provided as constant attributes of the hash objects returned by the constructors:

hash.**digest_size**

The size of the resulting hash in bytes.

hash.**block_size**

The internal block size of the hash algorithm in bytes.

A hash object has the following attributes:

hash.**name**

The canonical name of this hash, always lowercase and always suitable as a parameter to *new()* to create another hash of this type.

Changed in version 3.4: The name attribute has been present in CPython since its inception, but until Python 3.4 was not formally specified, so may not exist on some platforms.

A hash object has the following methods:

hash.**update**(*data*)

Update the hash object with the *bytes-like object*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

hash.**digest**()

Return the digest of the data passed to the *update()* method so far. This is a bytes object of size *digest_size* which may contain bytes in the whole range from 0 to 255.

hash.**hexdigest**()

Like *digest()* except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

hash.**copy**()

Return a copy ("clone") of the hash object. This can be used to efficiently compute the digests of data sharing a common initial substring.

15.1.6 SHAKE variable length digests

hashlib.**shake_128**([*data*,]*, *usedforsecurity=True*)

hashlib.**shake_256**([*data*,]*, *usedforsecurity=True*)

The *shake_128()* and *shake_256()* algorithms provide variable length digests with length_in_bits//2 up to 128 or 256 bits of security. As such, their digest methods require a length. Maximum length is not limited by the SHAKE algorithm.

shake.**digest**(*length*)

Return the digest of the data passed to the *update()* method so far. This is a bytes object of size *length* which may contain bytes in the whole range from 0 to 255.

shake.**hexdigest**(*length*)

Like *digest()* except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value in email or other non-binary environments.

Example use:

```
>>> h = hashlib.shake_256(b'Nobody inspects the spammish repetition')
>>> h.hexdigest(20)
'44709d6fcb83d92a76dcb0b668c98e1b1d3dafe7'
```

15.1.7 File hashing

The hashlib module provides a helper function for efficient hashing of a file or file-like object.

hashlib.**file_digest**(*fileobj*, *digest*, */*)

Return a digest object that has been updated with contents of file object.

fileobj must be a file-like object opened for reading in binary mode. It accepts file objects from builtin *open()*, *BytesIO* instances, SocketIO objects from *socket.socket.makefile()*, and similar. *fileobj* must be opened in blocking mode, otherwise a *BlockingIOError* may be raised.

The function may bypass Python's I/O and use the file descriptor from *fileno()* directly. *fileobj* must be assumed to be in an unknown state after this function returns or raises. It is up to the caller to close *fileobj*.

digest must either be a hash algorithm name as a *str*, a hash constructor, or a callable that returns a hash object.

Example:

```
>>> import io, hashlib, hmac
>>> with open("library/hashlib.rst", "rb") as f:
...     digest = hashlib.file_digest(f, "sha256")
...
>>> digest.hexdigest()
'...'
```

```
>>> buf = io.BytesIO(b"somedata")
>>> mac1 = hmac.HMAC(b"key", digestmod=hashlib.sha512)
>>> digest = hashlib.file_digest(buf, lambda: mac1)
```

```
>>> digest is mac1
True
>>> mac2 = hmac.HMAC(b"key", b"somedata", digestmod=hashlib.sha512)
>>> mac1.digest() == mac2.digest()
True
```

Added in version 3.11.

Changed in version 3.13.4: Now raises a *BlockingIOError* if the file is opened in blocking mode. Previously, spurious null bytes were added to the digest.

15.1.8 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a salt.

hashlib.**pbkdf2_hmac**(*hash_name*, *password*, *salt*, *iterations*, *dklen=None*)

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudorandom function.

The string *hash_name* is the desired name of the hash digest algorithm for HMAC, e.g. 'sha1' or 'sha256'. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

The number of *iterations* should be chosen based on the hash algorithm and computing power. As of 2022, hundreds of thousands of iterations of SHA-256 are suggested. For rationale as to why and how to choose what is best for your application, read *Appendix A.2.2* of NIST-SP-800-132. The answers on the stackexchange pbkdf2 iterations question explain in detail.

dklen is the length of the derived key in bytes. If *dklen* is `None` then the digest size of the hash algorithm *hash_name* is used, e.g. 64 for SHA-512.

```
>>> from hashlib import pbkdf2_hmac
>>> our_app_iters = 500_000  # Application specific, read above.
>>> dk = pbkdf2_hmac('sha256', b'password', b'bad salt' * 2, our_app_iters)
>>> dk.hex()
'15530bba69924174860db778f2c6f8104d3aaf9d26241840c8c4a641c8d000a9'
```

Function only available when Python is compiled with OpenSSL.

Added in version 3.4.

Changed in version 3.12: Function now only available when Python is built with OpenSSL. The slow pure Python implementation has been removed.

hashlib.**scrypt**(*password*, ***, *salt*, *n*, *r*, *p*, *maxmem=0*, *dklen=64*)

The function provides scrypt password-based key derivation function as defined in **RFC 7914**.

password and *salt* must be *bytes-like objects*. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

n is the CPU/Memory cost factor, *r* the block size, *p* parallelization factor and *maxmem* limits memory (OpenSSL 1.1.0 defaults to 32 MiB). *dklen* is the length of the derived key in bytes.

Added in version 3.6.

15.1.9 BLAKE2

BLAKE2 is a cryptographic hash function defined in **RFC 7693** that comes in two flavors:

- **BLAKE2b**, optimized for 64-bit platforms and produces digests of any size between 1 and 64 bytes,
- **BLAKE2s**, optimized for 8- to 32-bit platforms and produces digests of any size between 1 and 32 bytes.

BLAKE2 supports **keyed mode** (a faster and simpler replacement for HMAC), **salted hashing**, **personalization**, and **tree hashing**.

Hash objects from this module follow the API of standard library's `hashlib` objects.

Creating hash objects

New hash objects are created by calling constructor functions:

hashlib.**blake2b**(*data=b''*, ***, *digest_size=64*, *key=b''*, *salt=b''*, *person=b''*, *fanout=1*, *depth=1*, *leaf_size=0*, *node_offset=0*, *node_depth=0*, *inner_size=0*, *last_node=False*, *usedforsecurity=True*)

hashlib.**blake2s**(*data=b''*, ***, *digest_size=32*, *key=b''*, *salt=b''*, *person=b''*, *fanout=1*, *depth=1*, *leaf_size=0*, *node_offset=0*, *node_depth=0*, *inner_size=0*, *last_node=False*, *usedforsecurity=True*)

These functions return the corresponding hash objects for calculating BLAKE2b or BLAKE2s. They optionally take these general parameters:

- *data*: initial chunk of data to hash, which must be *bytes-like object*. It can be passed only as positional argument.
- *digest_size*: size of output digest in bytes.
- *key*: key for keyed hashing (up to 64 bytes for BLAKE2b, up to 32 bytes for BLAKE2s).
- *salt*: salt for randomized hashing (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).
- *person*: personalization string (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).

The following table shows limits for general parameters (in bytes):

Hash	digest_size	len(key)	len(salt)	len(person)
BLAKE2b	64	64	16	16
BLAKE2s	32	32	8	8

Note

BLAKE2 specification defines constant lengths for salt and personalization parameters, however, for convenience, this implementation accepts byte strings of any size up to the specified length. If the length of the parameter is less than specified, it is padded with zeros, thus, for example, `b'salt'` and `b'salt\x00'` is the same value. (This is not the case for *key*.)

These sizes are available as module *constants* described below.

Constructor functions also accept the following tree hashing parameters:

- *fanout*: fanout (0 to 255, 0 if unlimited, 1 in sequential mode).
- *depth*: maximal depth of tree (1 to 255, 255 if unlimited, 1 in sequential mode).
- *leaf_size*: maximal byte length of leaf (0 to `2**32-1`, 0 if unlimited or in sequential mode).
- *node_offset*: node offset (0 to `2**64-1` for BLAKE2b, 0 to `2**48-1` for BLAKE2s, 0 for the first, leftmost, leaf, or in sequential mode).
- *node_depth*: node depth (0 to 255, 0 for leaves, or in sequential mode).
- *inner_size*: inner digest size (0 to 64 for BLAKE2b, 0 to 32 for BLAKE2s, 0 in sequential mode).
- *last_node*: boolean indicating whether the processed node is the last one (`False` for sequential mode).

See section 2.10 in BLAKE2 specification for comprehensive review of tree hashing.

Constants

`blake2b.`**`SALT_SIZE`**

`blake2s.`**`SALT_SIZE`**

Salt length (maximum length accepted by constructors).

`blake2b.`**`PERSON_SIZE`**

`blake2s.`**`PERSON_SIZE`**

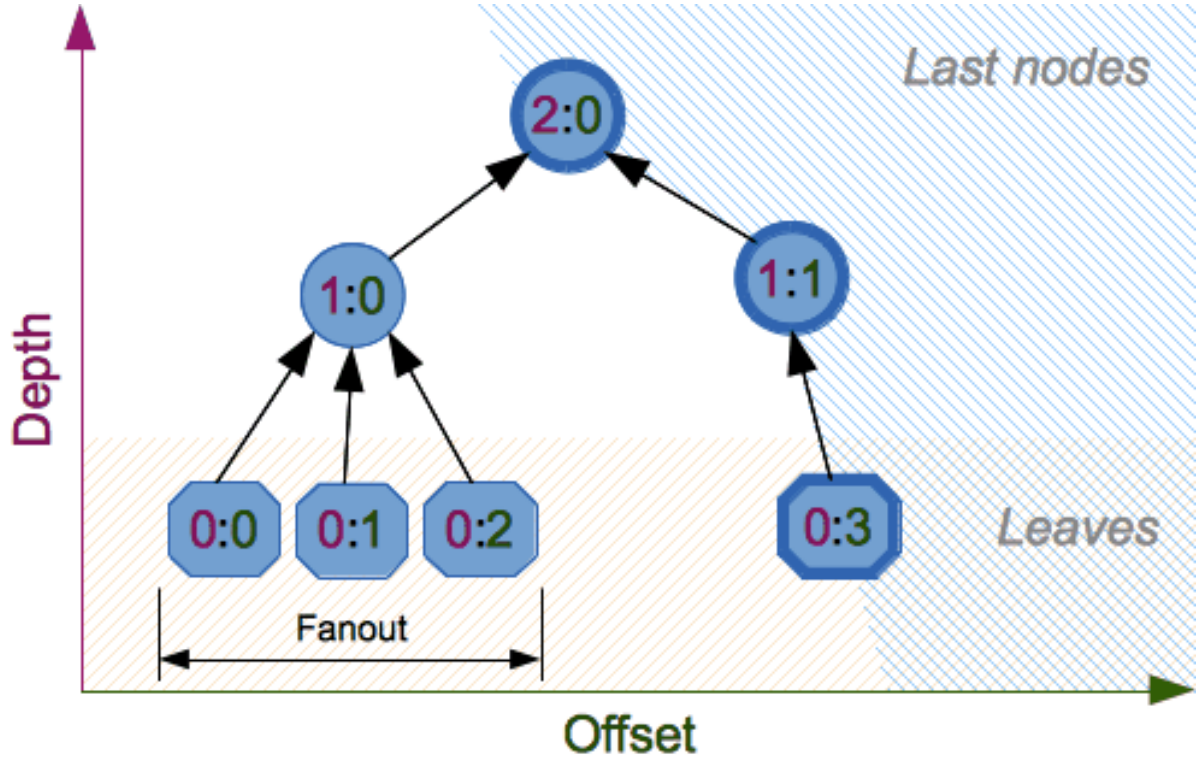
Personalization string length (maximum length accepted by constructors).

`blake2b.`**`MAX_KEY_SIZE`**

`blake2s.`**`MAX_KEY_SIZE`**

Maximum key size.

`blake2b.`**`MAX_DIGEST_SIZE`**



blake2s.**MAX_DIGEST_SIZE**

Maximum digest size that the hash function can output.

Examples

Simple hashing

To calculate hash of some data, you should first construct a hash object by calling the appropriate constructor function (*blake2b()* or *blake2s()*), then update it with the data by calling *update()* on the object, and, finally, get the digest out of the object by calling *digest()* (or *hexdigest()* for hex-encoded string).

```
>>> from hashlib import blake2b
>>> h = blake2b()
>>> h.update(b'Hello world')
>>> h.hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb4
↪'
```

As a shortcut, you can pass the first chunk of data to update directly to the constructor as the positional argument:

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb4
↪'
```

You can call *hash.update()* as many times as you need to iteratively update the hash:

```
>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
```

(continues on next page)

(continued from previous page)

```
>>> for item in items:
...     h.update(item)
...
>>> h.hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb4
↪'
```

Using different digest sizes

BLAKE2 has configurable size of digests up to 64 bytes for BLAKE2b and up to 32 bytes for BLAKE2s. For example, to replace SHA-1 with BLAKE2b without changing the size of output, we can tell BLAKE2b to produce 20-byte digests:

```
>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure function')
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20
```

Hash objects with different digest sizes have completely different outputs (shorter hashes are *not* prefixes of longer hashes); BLAKE2b and BLAKE2s produce different outputs even if the output length is the same:

```
>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fa1d8fcfd719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'
```

Keyed hashing

Keyed hashing can be used for authentication as a faster and simpler replacement for Hash-based message authentication code (HMAC). BLAKE2 can be securely used in prefix-MAC mode thanks to the indifferentiability property inherited from BLAKE.

This example shows how to get a (hex-encoded) 128-bit authentication code for message `b'message data'` with key `b'pseudorandom key'`:

```
>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363ff7401e02026f4a4687d4863ced'
```

As a practical example, a web application can symmetrically sign cookies sent to users and later verify them to make sure they weren't tampered with:

```
>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>
>>> SECRET_KEY = b'pseudorandomly generated server secret key'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{0},{1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False
```

Even though there's a native keyed hashing mode, BLAKE2 can, of course, be used in HMAC construction with *hmac* module:

```
>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2s)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0c861c8142'
```

Randomized hashing

By setting *salt* parameter users can introduce randomization to the hash function. Randomized hashing is useful for protecting against collision attacks on the hash function used in digital signatures.

> Randomized hashing is designed for situations where one party, the message preparer, generates all or part of a message to be signed by a second party, the message signer. If the message preparer is able to find cryptographic hash function collisions (i.e., two messages producing the same hash value), then they might prepare meaningful versions of the message that would produce the same hash value and digital signature, but with different results (e.g., transferring $1,000,000 to an account, rather than $10). Cryptographic hash functions have been designed with collision resistance as a major goal, but the current concentration on attacking cryptographic hash functions may result in a given cryptographic hash function providing less collision resistance than expected. Randomized hashing offers the signer additional protection by reducing the likelihood that a preparer can generate two or more messages that ultimately yield the same hash value during the digital signature generation process — even if it is practical to find collisions for the hash function. However, the use of randomized hashing may reduce the amount of security provided by a digital signature when all portions of the message are prepared by the signer.
>
> (NIST SP-800-106 "Randomized Hashing for Digital Signatures")

In BLAKE2 the salt is processed as a one-time input to the hash function during initialization, rather than as an input to each compression function.

Warning

Salted hashing (or just hashing) with BLAKE2 or any other general-purpose cryptographic hash function, such as SHA-256, is not suitable for hashing passwords. See BLAKE2 FAQ for more information.

```
>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'
>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random salt.
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True
```

Personalization

Sometimes it is useful to force hash function to produce different digests for the same input for different purposes. Quoting the authors of the Skein hash function:

> We recommend that all application designers seriously consider doing this; we have seen many protocols where a hash that is computed in one part of the protocol can be used in an entirely different part because two hash computations were done on similar or related data, and the attacker can force the application to make the hash inputs the same. Personalizing each hash function used in the protocol summarily stops this type of attack.
>
> (The Skein Hash Function Family, p. 21)

BLAKE2 can be personalized by passing bytes to the *person* argument:

```
>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf2676095d3b4'
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bfb2c4c9aea52264a80b75005e65619778de59f383a3'
```

Personalization together with the keyed mode can also be used to derive different keys from a single one.

```
>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy5OZothY+kHY6h21KM=')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWPlYk1e/nWfu0WSEb0KRcjhDeP/o=
```

Tree mode

Here's an example of hashing a minimal tree with two leaf nodes:

```
  10
 /  \
00  01
```

This example uses 64-byte internal digests, and returns the 32-byte final digest:

```
>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=0, last_node=False)
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=1, node_depth=0, last_node=True)
>>> # Root node
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=1, last_node=True)
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
>>> h10.hexdigest()
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95e881db5aa'
```

Credits

BLAKE2 was designed by *Jean-Philippe Aumasson*, *Samuel Neves*, *Zooko Wilcox-O'Hearn*, and *Christian Winnerlein* based on SHA-3 finalist BLAKE created by *Jean-Philippe Aumasson*, *Luca Henzen*, *Willi Meier*, and *Raphael C.-W. Phan*.

It uses core algorithm from ChaCha cipher designed by *Daniel J. Bernstein*.

The stdlib implementation is based on pyblake2 module. It was written by *Dmitry Chestnykh* based on C implementation written by *Samuel Neves*. The documentation was copied from pyblake2 and written by *Dmitry Chestnykh*.

The C code was partly rewritten for Python by *Christian Heimes*.

The following public domain dedication applies for both C hash function implementation, extension code, and this documentation:

15.2 `hmac` — Keyed-Hashing for Message Authentication

Source code: Lib/hmac.py

This module implements the HMAC algorithm as described by **RFC 2104**.

`hmac.new`(*key*, *msg=None*, *digestmod*)

Return a new hmac object. *key* is a bytes or bytearray object giving the secret key. If *msg* is present, the method call `update(msg)` is made. *digestmod* is the digest name, digest constructor or module for the HMAC object to use. It may be any name suitable to *hashlib.new()*. Despite its argument position, it is required.

Changed in version 3.4: Parameter *key* can be a bytes or bytearray object. Parameter *msg* can be of any type supported by *hashlib*. Parameter *digestmod* can be the name of a hash algorithm.

Changed in version 3.8: The *digestmod* argument is now required. Pass it as a keyword argument to avoid awkwardness when you do not have an initial *msg*.

`hmac.digest`(*key*, *msg*, *digest*)

Return digest of *msg* for given secret *key* and *digest*. The function is equivalent to `HMAC(key, msg, digest).digest()`, but uses an optimized C or inline implementation, which is faster for messages that fit into memory. The parameters *key*, *msg*, and *digest* have the same meaning as in *new()*.

CPython implementation detail, the optimized C implementation is only used when *digest* is a string and name of a digest algorithm, which is supported by OpenSSL.

Added in version 3.7.

An HMAC object has the following methods:

`HMAC.update`(*msg*)

Update the hmac object with *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a + b)`.

Changed in version 3.4: Parameter *msg* can be of any type supported by *hashlib*.

HMAC.**digest**()

Return the digest of the bytes passed to the *update()* method so far. This bytes object will be the same length as the *digest_size* of the digest given to the constructor. It may contain non-ASCII bytes, including NUL bytes.

> **Warning**
>
> When comparing the output of *digest()* to an externally supplied digest during a verification routine, it is recommended to use the *compare_digest()* function instead of the == operator to reduce the vulnerability to timing attacks.

HMAC.**hexdigest**()

Like *digest()* except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

> **Warning**
>
> When comparing the output of *hexdigest()* to an externally supplied digest during a verification routine, it is recommended to use the *compare_digest()* function instead of the == operator to reduce the vulnerability to timing attacks.

HMAC.**copy**()

Return a copy ("clone") of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

A hash object has the following attributes:

HMAC.**digest_size**

The size of the resulting HMAC digest in bytes.

HMAC.**block_size**

The internal block size of the hash algorithm in bytes.

Added in version 3.4.

HMAC.**name**

The canonical name of this HMAC, always lowercase, e.g. `hmac-md5`.

Added in version 3.4.

Changed in version 3.10: Removed the undocumented attributes `HMAC.digest_cons`, `HMAC.inner`, and `HMAC.outer`.

This module also provides the following helper function:

hmac.**compare_digest**(*a*, *b*)

Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type: either *str* (ASCII only, as e.g. returned by *HMAC.hexdigest()*), or a *bytes-like object*.

> **Note**
>
> If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

Added in version 3.3.

Changed in version 3.10: The function uses OpenSSL's `CRYPTO_memcmp()` internally when available.

Module ***hashlib***
The Python module providing secure hash functions.

15.3 `secrets` — Generate secure random numbers for managing secrets

Added in version 3.6.

Source code: Lib/secrets.py

The *secrets* module is used for generating cryptographically strong random numbers suitable for managing data such as passwords, account authentication, security tokens, and related secrets.

In particular, *secrets* should be used in preference to the default pseudo-random number generator in the *random* module, which is designed for modelling and simulation, not security or cryptography.

See also

PEP 506

15.3.1 Random numbers

The *secrets* module provides access to the most secure source of randomness that your operating system provides.

class secrets.**SystemRandom**
A class for generating random numbers using the highest-quality sources provided by the operating system. See *random.SystemRandom* for additional details.

secrets.**choice**(*seq*)
Return a randomly chosen element from a non-empty sequence.

secrets.**randbelow**(*exclusive_upper_bound*)
Return a random int in the range [0, *exclusive_upper_bound*).

secrets.**randbits**(*k*)
Return a non-negative int with *k* random bits.

15.3.2 Generating tokens

The *secrets* module provides functions for generating secure tokens, suitable for applications such as password resets, hard-to-guess URLs, and similar.

secrets.**token_bytes**([*nbytes=None*])
Return a random byte string containing *nbytes* number of bytes. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_bytes(16)
b'\xebr\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

secrets.**token_hex**([*nbytes=None*])
Return a random text string, in hexadecimal. The string has *nbytes* random bytes, each byte converted to two hex digits. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

secrets.**token_urlsafe**([*nbytes=None*])

Return a random URL-safe text string, containing *nbytes* random bytes. The text is Base64 encoded, so on average each byte results in approximately 1.3 characters. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_urlsafe(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

How many bytes should tokens use?

To be secure against brute-force attacks, tokens need to have sufficient randomness. Unfortunately, what is considered sufficient will necessarily increase as computers get more powerful and able to make more guesses in a shorter period. As of 2015, it is believed that 32 bytes (256 bits) of randomness is sufficient for the typical use-case expected for the *secrets* module.

For those who want to manage their own token length, you can explicitly specify how much randomness is used for tokens by giving an *int* argument to the various `token_*` functions. That argument is taken as the number of bytes of randomness to use.

Otherwise, if no argument is provided, or if the argument is `None`, the `token_*` functions will use a reasonable default instead.

Note

That default is subject to change at any time, including during maintenance releases.

15.3.3 Other functions

secrets.**compare_digest**(*a*, *b*)

Return `True` if strings or *bytes-like objects* *a* and *b* are equal, otherwise `False`, using a "constant-time compare" to reduce the risk of timing attacks. See *hmac.compare_digest()* for additional details.

15.3.4 Recipes and best practices

This section shows recipes and best practices for using *secrets* to manage a basic level of security.

Generate an eight-character alphanumeric password:

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
password = ''.join(secrets.choice(alphabet) for i in range(8))
```

Note

Applications should not **store passwords in a recoverable format**, whether plain text or encrypted. They should be salted and hashed using a cryptographically strong one-way (irreversible) hash function.

Generate a ten-character alphanumeric password with at least one lowercase character, at least one uppercase character, and at least three digits:

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
while True:
    password = ''.join(secrets.choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
            and any(c.isupper() for c in password)
            and sum(c.isdigit() for c in password) >= 3):
        break
```

Generate an XKCD-style passphrase:

```
import secrets
# On standard Linux systems, use a convenient dictionary file.
# Other platforms may need to provide their own word-list.
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
    password = ' '.join(secrets.choice(words) for i in range(4))
```

Generate a hard-to-guess temporary URL containing a security token suitable for password recovery applications:

```
import secrets
url = 'https://example.com/reset=' + secrets.token_urlsafe()
```

CHAPTER

SIXTEEN

GENERIC OPERATING SYSTEM SERVICES

The modules described in this chapter provide interfaces to operating system features that are available on (almost) all operating systems, such as files and a clock. The interfaces are generally modeled after the Unix or C interfaces, but they are available on most other systems as well. Here's an overview:

16.1 os — Miscellaneous operating system interfaces

Source code: Lib/os.py

This module provides a portable way of using operating system dependent functionality. If you just want to read or write a file see *open()*, if you want to manipulate paths, see the *os.path* module, and if you want to read all the lines in all the files on the command line see the *fileinput* module. For creating temporary files and directories see the *tempfile* module, and for high-level file and directory handling see the *shutil* module.

Notes on the availability of these functions:

- The design of all built-in operating system dependent modules of Python is such that as long as the same functionality is available, it uses the same interface; for example, the function `os.stat(path)` returns stat information about *path* in the same format (which happens to have originated with the POSIX interface).
- Extensions peculiar to a particular operating system are also available through the *os* module, but using them is of course a threat to portability.
- All functions accepting path or file names accept both bytes and string objects, and result in an object of the same type, if a path or file name is returned.
- On VxWorks, os.popen, os.fork, os.execv and os.spawn*p* are not supported.
- On WebAssembly platforms, Android and iOS, large parts of the *os* module are not available or behave differently. APIs related to processes (e.g. *fork()*, *execve()*) and resources (e.g. *nice()*) are not available. Others like *getuid()* and *getpid()* are emulated or stubs. WebAssembly platforms also lack support for signals (e.g. *kill()*, *wait()*).

> **Note**
>
> All functions in this module raise *OSError* (or subclasses thereof) in the case of invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.

exception `os.error`

An alias for the built-in *OSError* exception.

`os.name`

The name of the operating system dependent module imported. The following names have currently been registered: `'posix'`, `'nt'`, `'java'`.

> **See also**
>
> *sys.platform* has a finer granularity. *os.uname()* gives system-dependent version information.
>
> The *platform* module provides detailed checks for the system's identity.

16.1.1 File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the *filesystem encoding and error handler* to perform this conversion (see *sys.getfilesystemencoding()*).

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

Changed in version 3.1: On some systems, conversion using the file system encoding may fail. In this case, Python uses the *surrogateescape encoding error handler*, which means that undecodable bytes are replaced by a Unicode character U+DC*xx* on decoding, and these are again translated to the original byte on encoding.

The *file system encoding* must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions can raise *UnicodeError*.

See also the *locale encoding*.

16.1.2 Python UTF-8 Mode

Added in version 3.7: See **PEP 540** for more details.

The Python UTF-8 Mode ignores the *locale encoding* and forces the usage of the UTF-8 encoding:

- Use UTF-8 as the *filesystem encoding*.
- *sys.getfilesystemencoding()* returns `'utf-8'`.
- *locale.getpreferredencoding()* returns `'utf-8'` (the *do_setlocale* argument has no effect).
- *sys.stdin*, *sys.stdout*, and *sys.stderr* all use UTF-8 as their text encoding, with the `surrogateescape` *error handler* being enabled for *sys.stdin* and *sys.stdout* (*sys.stderr* continues to use `backslashreplace` as it does in the default locale-aware mode)
- On Unix, *os.device_encoding()* returns `'utf-8'` rather than the device encoding.

Note that the standard stream settings in UTF-8 mode can be overridden by `PYTHONIOENCODING` (just as they can be in the default locale-aware mode).

As a consequence of the changes in those lower level APIs, other higher level APIs also exhibit different default behaviours:

- Command line arguments, environment variables and filenames are decoded to text using the UTF-8 encoding.
- *os.fsdecode()* and *os.fsencode()* use the UTF-8 encoding.
- *open()*, *io.open()*, and *codecs.open()* use the UTF-8 encoding by default. However, they still use the strict error handler by default so that attempting to open a binary file in text mode is likely to raise an exception rather than producing nonsense data.

The *Python UTF-8 Mode* is enabled if the LC_CTYPE locale is `C` or `POSIX` at Python startup (see the `PyConfig_Read()` function).

It can be enabled or disabled using the `-X utf8` command line option and the `PYTHONUTF8` environment variable.

If the `PYTHONUTF8` environment variable is not set at all, then the interpreter defaults to using the current locale settings, *unless* the current locale is identified as a legacy ASCII-based locale (as described for `PYTHONCOERCECLOCALE`), and locale coercion is either disabled or fails. In such legacy locales, the interpreter will default to enabling UTF-8 mode unless explicitly instructed not to do so.

The Python UTF-8 Mode can only be enabled at the Python startup. Its value can be read from *sys.flags.utf8_mode*.

See also the UTF-8 mode on Windows and the *filesystem encoding and error handler*.

See also

PEP 686
Python 3.15 will make *Python UTF-8 Mode* default.

16.1.3 Process Parameters

These functions and data items provide information and operate on the current process and user.

`os.ctermid()`

Return the filename corresponding to the controlling terminal of the process.

Availability: Unix, not WASI.

`os.environ`

A *mapping* object where keys and values are strings that represent the process environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the *os* module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in *os.environ*, except for changes made by modifying *os.environ* directly.

This mapping may be used to modify the environment as well as query the environment. *putenv()* will be called automatically when the mapping is modified.

On Unix, keys and values use *sys.getfilesystemencoding()* and `'surrogateescape'` error handler. Use *environb* if you would like to use a different encoding.

On Windows, the keys are converted to uppercase. This also applies when getting, setting, or deleting an item. For example, `environ['monty'] = 'python'` maps the key `'MONTY'` to the value `'python'`.

Note

Calling *putenv()* directly does not change *os.environ*, so it's better to modify *os.environ*.

Note

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

You can delete items in this mapping to unset environment variables. *unsetenv()* will be called automatically when an item is deleted from *os.environ*, and when one of the `pop()` or `clear()` methods is called.

Changed in version 3.9: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

`os.environb`

Bytes version of *environ*: a *mapping* object where both keys and values are *bytes* objects representing the process environment. *environ* and *environb* are synchronized (modifying *environb* updates *environ*, and vice versa).

environb is only available if *supports_bytes_environ* is `True`.

Added in version 3.2.

Changed in version 3.9: Updated to support **PEP 584**'s merge (|) and update (|=) operators.

os.**chdir**(*path*)

os.**fchdir**(*fd*)

os.**getcwd**()

These functions are described in *Files and Directories*.

os.**fsencode**(*filename*)

Encode *path-like filename* to the *filesystem encoding and error handler*; return `bytes` unchanged.

`fsdecode()` is the reverse function.

Added in version 3.2.

Changed in version 3.6: Support added to accept objects implementing the `os.PathLike` interface.

os.**fsdecode**(*filename*)

Decode the *path-like filename* from the *filesystem encoding and error handler*; return `str` unchanged.

`fsencode()` is the reverse function.

Added in version 3.2.

Changed in version 3.6: Support added to accept objects implementing the `os.PathLike` interface.

os.**fspath**(*path*)

Return the file system representation of the path.

If `str` or `bytes` is passed in, it is returned unchanged. Otherwise `__fspath__()` is called and its value is returned as long as it is a `str` or `bytes` object. In all other cases, `TypeError` is raised.

Added in version 3.6.

class os.**PathLike**

An *abstract base class* for objects representing a file system path, e.g. `pathlib.PurePath`.

Added in version 3.6.

abstractmethod **__fspath__**()

Return the file system path representation of the object.

The method should only return a `str` or `bytes` object, with the preference being for `str`.

os.**getenv**(*key*, *default=None*)

Return the value of the environment variable *key* as a string if it exists, or *default* if it doesn't. *key* is a string. Note that since `getenv()` uses `os.environ`, the mapping of `getenv()` is similarly also captured on import, and the function may not reflect future environment changes.

On Unix, keys and values are decoded with `sys.getfilesystemencoding()` and `'surrogateescape'` error handler. Use `os.getenvb()` if you would like to use a different encoding.

Availability: Unix, Windows.

os.**getenvb**(*key*, *default=None*)

Return the value of the environment variable *key* as bytes if it exists, or *default* if it doesn't. *key* must be bytes. Note that since `getenvb()` uses `os.environb`, the mapping of `getenvb()` is similarly also captured on import, and the function may not reflect future environment changes.

`getenvb()` is only available if `supports_bytes_environ` is `True`.

Availability: Unix.

Added in version 3.2.

os.**get_exec_path**(*env=None*)

Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is `None`, *environ* is used.

Added in version 3.2.

os.**getegid**()

Return the effective group id of the current process. This corresponds to the "set id" bit on the file being executed in the current process.

Availability: Unix, not WASI.

os.**geteuid**()

Return the current process's effective user id.

Availability: Unix, not WASI.

os.**getgid**()

Return the real group id of the current process.

Availability: Unix.

The function is a stub on WASI, see *WebAssembly platforms* for more information.

os.**getgrouplist**(*user*, *group*, */*)

Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*, because that group ID will otherwise be potentially omitted.

Availability: Unix, not WASI.

Added in version 3.3.

os.**getgroups**()

Return list of supplemental group ids associated with the current process.

Availability: Unix, not WASI.

> **Note**
>
> On macOS, *getgroups()* behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of `10.5` or earlier, *getgroups()* returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to *setgroups()* if suitably privileged. If built with a deployment target greater than `10.5`, *getgroups()* returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to *setgroups()*, and its length is not limited to 16. The deployment target value, `MACOSX_DEPLOYMENT_TARGET`, can be obtained with *sysconfig.get_config_var()*.

os.**getlogin**()

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use *getpass.getuser()* since the latter checks the environment variables `LOGNAME` or `USERNAME` to find out who the user is, and falls back to `pwd.getpwuid(os.getuid())[0]` to get the login name of the current real user id.

Availability: Unix, Windows, not WASI.

os.**getpgid**(*pid*)

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

Availability: Unix, not WASI.

os.**getpgrp**()

Return the id of the current process group.

Availability: Unix, not WASI.

os.**getpid**()

Return the current process id.

The function is a stub on WASI, see *WebAssembly platforms* for more information.

os.**getppid**()

Return the parent's process id. When the parent process has exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

Availability: Unix, Windows, not WASI.

Changed in version 3.2: Added support for Windows.

os.**getpriority**(*which*, *who*)

Get program scheduling priority. The value *which* is one of *PRIO_PROCESS*, *PRIO_PGRP*, or *PRIO_USER*, and *who* is interpreted relative to *which* (a process identifier for *PRIO_PROCESS*, process group identifier for *PRIO_PGRP*, and a user ID for *PRIO_USER*). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

Availability: Unix, not WASI.

Added in version 3.3.

os.**PRIO_PROCESS**

os.**PRIO_PGRP**

os.**PRIO_USER**

Parameters for the *getpriority()* and *setpriority()* functions.

Availability: Unix, not WASI.

Added in version 3.3.

os.**PRIO_DARWIN_THREAD**

os.**PRIO_DARWIN_PROCESS**

os.**PRIO_DARWIN_BG**

os.**PRIO_DARWIN_NONUI**

Parameters for the *getpriority()* and *setpriority()* functions.

Availability: macOS

Added in version 3.12.

os.**getresuid**()

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

Availability: Unix, not WASI.

Added in version 3.2.

os.**getresgid**()

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

Availability: Unix, not WASI.

Added in version 3.2.

os.**getuid**()

Return the current process's real user id.

Availability: Unix.

The function is a stub on WASI, see *WebAssembly platforms* for more information.

os.**initgroups**(*username*, *gid*, /)

Call the system initgroups() to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

Availability: Unix, not WASI, not Android.

Added in version 3.2.

os.**putenv**(*key*, *value*, /)

Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Assignments to items in `os.environ` are automatically translated into corresponding calls to `putenv()`; however, calls to `putenv()` don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`. This also applies to `getenv()` and `getenvb()`, which respectively use `os.environ` and `os.environb` in their implementations.

> **Note**
>
> On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

Raises an *auditing event* `os.putenv` with arguments `key`, `value`.

Changed in version 3.9: The function is now always available.

os.**setegid**(*egid*, /)

Set the current process's effective group id.

Availability: Unix, not WASI, not Android.

os.**seteuid**(*euid*, /)

Set the current process's effective user id.

Availability: Unix, not WASI, not Android.

os.**setgid**(*gid*, /)

Set the current process' group id.

Availability: Unix, not WASI, not Android.

os.**setgroups**(*groups*, /)

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

Availability: Unix, not WASI.

> **Note**
>
> On macOS, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for `getgroups()` for cases where it may not return the same group list set by calling setgroups().

os.**setns**(*fd*, *nstype=0*)

Reassociate the current thread with a Linux namespace. See the `setns(2)` and `namespaces(7)` man pages for more details.

If *fd* refers to a `/proc/pid/ns/` link, `setns()` reassociates the calling thread with the namespace associated with that link, and *nstype* may be set to one of the *CLONE_NEW* constants* to impose constraints on the operation (`0` means no constraints).

Since Linux 5.8, *fd* may refer to a PID file descriptor obtained from `pidfd_open()`. In this case, `setns()` reassociates the calling thread into one or more of the same namespaces as the thread referred to by *fd*. This is subject to any constraints imposed by *nstype*, which is a bit mask combining one or more of the *CLONE_NEW* constants*, e.g. `setns(fd, os.CLONE_NEWUTS | os.CLONE_NEWPID)`. The caller's memberships in unspecified namespaces are left unchanged.

fd can be any object with a `fileno()` method, or a raw file descriptor.

This example reassociates the thread with the `init` process's network namespace:

```
fd = os.open("/proc/1/ns/net", os.O_RDONLY)
os.setns(fd, os.CLONE_NEWNET)
os.close(fd)
```

Availability: Linux >= 3.0 with glibc >= 2.14.

Added in version 3.12.

See also

The `unshare()` function.

`os.`**`setpgrp`**`()`

Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

Availability: Unix, not WASI.

`os.`**`setpgid`**`(`*pid*, *pgrp*, `/`)

Call the system call `setpgid()` to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

Availability: Unix, not WASI.

`os.`**`setpriority`**`(`*which*, *who*, *priority*`)`

Set program scheduling priority. The value *which* is one of `PRIO_PROCESS`, `PRIO_PGRP`, or `PRIO_USER`, and *who* is interpreted relative to *which* (a process identifier for `PRIO_PROCESS`, process group identifier for `PRIO_PGRP`, and a user ID for `PRIO_USER`). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

Availability: Unix, not WASI.

Added in version 3.3.

`os.`**`setregid`**`(`*rgid*, *egid*, `/`)

Set the current process's real and effective group ids.

Availability: Unix, not WASI, not Android.

`os.`**`setresgid`**`(`*rgid*, *egid*, *sgid*, `/`)

Set the current process's real, effective, and saved group ids.

Availability: Unix, not WASI, not Android.

Added in version 3.2.

`os.`**`setresuid`**`(`*ruid*, *euid*, *suid*, `/`)

Set the current process's real, effective, and saved user ids.

Availability: Unix, not WASI, not Android.

Added in version 3.2.

os.**setreuid**(*ruid*, *euid*, /)

Set the current process's real and effective user ids.

Availability: Unix, not WASI, not Android.

os.**getsid**(*pid*, /)

Call the system call `getsid()`. See the Unix manual for the semantics.

Availability: Unix, not WASI.

os.**setsid**()

Call the system call `setsid()`. See the Unix manual for the semantics.

Availability: Unix, not WASI.

os.**setuid**(*uid*, /)

Set the current process's user id.

Availability: Unix, not WASI, not Android.

os.**strerror**(*code*, /)

Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, *`ValueError`* is raised.

os.**supports_bytes_environ**

`True` if the native OS type of the environment is bytes (eg. `False` on Windows).

Added in version 3.2.

os.**umask**(*mask*, /)

Set the current numeric umask and return the previous umask.

The function is a stub on WASI, see *WebAssembly platforms* for more information.

os.**uname**()

Returns information identifying the current operating system. The return value is an object with five attributes:

- `sysname` - operating system name
- `nodename` - name of machine on network (implementation-defined)
- `release` - operating system release
- `version` - operating system version
- `machine` - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing `sysname`, `nodename`, `release`, `version`, and `machine` in that order.

Some systems truncate `nodename` to 8 characters or to the leading component; a better way to get the hostname is *`socket.gethostname()`* or even `socket.gethostbyaddr(socket.gethostname())`.

On macOS, iOS and Android, this returns the *kernel* name and version (i.e., `'Darwin'` on macOS and iOS; `'Linux'` on Android). *`platform.uname()`* can be used to get the user-facing operating system name and version on iOS and Android.

Availability: Unix.

Changed in version 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

os.**unsetenv**(*key*, /)

Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with *`os.system()`*, *`popen()`* or *`fork()`* and *`execv()`*.

Deletion of items in *`os.environ`* is automatically translated into a corresponding call to *`unsetenv()`*; however, calls to *`unsetenv()`* don't update *`os.environ`*, so it is actually preferable to delete items of *`os.environ`*.

Raises an *auditing event* `os.unsetenv` with argument `key`.

Changed in version 3.9: The function is now always available and is also available on Windows.

`os.`**`unshare`**(*flags*)

Disassociate parts of the process execution context, and move them into a newly created namespace. See the *unshare(2)* man page for more details. The *flags* argument is a bit mask, combining zero or more of the *CLONE_* constants*, that specifies which parts of the execution context should be unshared from their existing associations and moved to a new namespace. If the *flags* argument is `0`, no changes are made to the calling process's execution context.

Availability: Linux >= 2.6.16.

Added in version 3.12.

See also

The *setns()* function.

Flags to the *unshare()* function, if the implementation supports them. See *unshare(2)* in the Linux manual for their exact effect and availability.

`os.`**`CLONE_FILES`**

`os.`**`CLONE_FS`**

`os.`**`CLONE_NEWCGROUP`**

`os.`**`CLONE_NEWIPC`**

`os.`**`CLONE_NEWNET`**

`os.`**`CLONE_NEWNS`**

`os.`**`CLONE_NEWPID`**

`os.`**`CLONE_NEWTIME`**

`os.`**`CLONE_NEWUSER`**

`os.`**`CLONE_NEWUTS`**

`os.`**`CLONE_SIGHAND`**

`os.`**`CLONE_SYSVSEM`**

`os.`**`CLONE_THREAD`**

`os.`**`CLONE_VM`**

16.1.4 File Object Creation

These functions create new *file objects*. (See also *open()* for opening file descriptors.)

`os.`**`fdopen`**(*fd*, **args*, ***kwargs*)

Return an open file object connected to the file descriptor *fd*. This is an alias of the *open()* built-in function and accepts the same arguments. The only difference is that the first argument of *fdopen()* must always be an integer.

16.1.5 File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name "file descriptor" is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The *fileno()* method can be used to obtain the file descriptor associated with a *file object* when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

os.**close**(*fd*)

Close file descriptor *fd*.

> **Note**
>
> This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To close a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, use its `close()` method.

os.**closerange**(*fd_low*, *fd_high*, */*)

Close all file descriptors from *fd_low* (inclusive) to *fd_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

os.**copy_file_range**(*src*, *dst*, *count*, *offset_src=None*, *offset_dst=None*)

Copy *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. If *offset_src* is `None`, then *src* is read from the current position; respectively for *offset_dst*.

In Linux kernel older than 5.3, the files pointed to by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with `errno` set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations, such as the use of reflinks (i.e., two or more inodes that share pointers to the same copy-on-write disk blocks; supported file systems include btrfs and XFS) and server-side copy (in the case of NFS).

The function copies bytes between two file descriptors. Text options, like the encoding and the line ending, are ignored.

The return value is the amount of bytes copied. This could be less than the amount requested.

> **Note**
>
> On Linux, `os.copy_file_range()` should not be used for copying a range of a pseudo file from a special filesystem like procfs and sysfs. It will always copy no bytes and return 0 as if the file was empty because of a known Linux kernel issue.

Availability: Linux >= 4.5 with glibc >= 2.27.

Added in version 3.8.

os.**device_encoding**(*fd*)

Return a string describing the encoding of the device associated with *fd* if it is connected to a terminal; else return `None`.

On Unix, if the *Python UTF-8 Mode* is enabled, return `'UTF-8'` rather than the device encoding.

Changed in version 3.10: On Unix, the function now implements the Python UTF-8 Mode.

os.**dup**(*fd*, */*)

Return a duplicate of file descriptor *fd*. The new file descriptor is *non-inheritable*.

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is *inheritable*.

Availability: not WASI.

Changed in version 3.4: The new file descriptor is now non-inheritable.

os.**dup2**(*fd*, *fd2*, *inheritable=True*)

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is *inheritable* by default or non-inheritable if *inheritable* is `False`.

Availability: not WASI.

Changed in version 3.4: Add the optional *inheritable* parameter.

Changed in version 3.7: Return *fd2* on success. Previously, `None` was always returned.

os.**fchmod**(*fd*, *mode*)

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for *chmod()* for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

Availability: Unix, Windows.

The function is limited on WASI, see *WebAssembly platforms* for more information.

Changed in version 3.13: Added support on Windows.

os.**fchown**(*fd*, *uid*, *gid*)

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1. See *chown()*. As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

The function is limited on WASI, see *WebAssembly platforms* for more information.

os.**fdatasync**(*fd*)

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

Availability: Unix.

Note

This function is not available on MacOS.

os.**fpathconf**(*fd*, *name*, */*)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

Availability: Unix.

os.**fstat**(*fd*)

Get the status of the file descriptor *fd*. Return a *stat_result* object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

See also

The *stat()* function.

os.**fstatvfs**(*fd*, /)

Return information about the filesystem containing the file associated with file descriptor *fd*, like *statvfs()*. As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

Availability: Unix.

os.**fsync**(*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native `fsync()` function; on Windows, the MS `_commit()` function.

If you're starting with a buffered Python *file object* *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

Availability: Unix, Windows.

os.**ftruncate**(*fd*, *length*, /)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Raises an *auditing event* `os.truncate` with arguments `fd`, `length`.

Availability: Unix, Windows.

Changed in version 3.5: Added support for Windows

os.**get_blocking**(*fd*, /)

Get the blocking mode of the file descriptor: `False` if the *O_NONBLOCK* flag is set, `True` if the flag is cleared.

See also *set_blocking()* and *socket.socket.setblocking()*.

Availability: Unix, Windows.

The function is limited on WASI, see *WebAssembly platforms* for more information.

On Windows, this function is limited to pipes.

Added in version 3.5.

Changed in version 3.12: Added support for pipes on Windows.

os.**grantpt**(*fd*, /)

Grant access to the slave pseudo-terminal device associated with the master pseudo-terminal device to which the file descriptor *fd* refers. The file descriptor *fd* is not closed upon failure.

Calls the C standard library function `grantpt()`.

Availability: Unix, not WASI.

Added in version 3.13.

os.**isatty**(*fd*, /)

Return `True` if the file descriptor *fd* is open and connected to a tty(-like) device, else `False`.

os.**lockf**(*fd*, *cmd*, *len*, /)

Apply, test or remove a POSIX lock on an open file descriptor. *fd* is an open file descriptor. *cmd* specifies the command to use - one of *F_LOCK*, *F_TLOCK*, *F_ULOCK* or *F_TEST*. *len* specifies the section of the file to lock.

Raises an *auditing event* `os.lockf` with arguments `fd`, `cmd`, `len`.

Availability: Unix.

Added in version 3.3.

os.**F_LOCK**

os.**F_TLOCK**

os.**F_ULOCK**

os.**F_TEST**

Flags that specify what action *lockf()* will take.

Availability: Unix.

Added in version 3.3.

os.**login_tty**(*fd*, /)

Prepare the tty of which fd is a file descriptor for a new login session. Make the calling process a session leader; make the tty the controlling tty, the stdin, the stdout, and the stderr of the calling process; close fd.

Availability: Unix, not WASI.

Added in version 3.11.

os.**lseek**(*fd*, *pos*, *whence*, /)

Set the current position of file descriptor *fd* to position *pos*, modified by *whence*, and return the new position in bytes relative to the start of the file. Valid values for *whence* are:

- *SEEK_SET* or 0 – set *pos* relative to the beginning of the file
- *SEEK_CUR* or 1 – set *pos* relative to the current file position
- *SEEK_END* or 2 – set *pos* relative to the end of the file
- *SEEK_HOLE* – set *pos* to the next data location, relative to *pos*
- *SEEK_DATA* – set *pos* to the next data hole, relative to *pos*

Changed in version 3.3: Add support for SEEK_HOLE and SEEK_DATA.

os.**SEEK_SET**

os.**SEEK_CUR**

os.**SEEK_END**

Parameters to the *lseek()* function and the *seek()* method on *file-like objects*, for whence to adjust the file position indicator.

SEEK_SET
Adjust the file position relative to the beginning of the file.

SEEK_CUR
Adjust the file position relative to the current file position.

SEEK_END
Adjust the file position relative to the end of the file.

Their values are 0, 1, and 2, respectively.

os.**SEEK_HOLE**

os.**SEEK_DATA**

Parameters to the *lseek()* function and the *seek()* method on *file-like objects*, for seeking file data and holes on sparsely allocated files.

SEEK_DATA
Adjust the file offset to the next location containing data, relative to the seek position.

SEEK_HOLE
Adjust the file offset to the next location containing a hole, relative to the seek position. A hole is defined as a sequence of zeros.

> **Note**
>
> These operations only make sense for filesystems that support them.

Availability: Linux >= 3.1, macOS, Unix

Added in version 3.3.

os.**open**(*path*, *flags*, *mode=0o777*, *, *dir_fd=None*)

Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*. When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is *non-inheritable*.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like *O_RDONLY* and *O_WRONLY*) are defined in the *os* module. In particular, on Windows adding *O_BINARY* is needed to open files in binary mode.

This function can support *paths relative to directory descriptors* with the *dir_fd* parameter.

Raises an *auditing event* `open` with arguments `path`, `mode`, `flags`.

Changed in version 3.4: The new file descriptor is now non-inheritable.

> **Note**
>
> This function is intended for low-level I/O. For normal usage, use the built-in function *open()*, which returns a *file object* with `read()` and `write()` methods (and many more). To wrap a file descriptor in a file object, use *fdopen()*.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

Changed in version 3.6: Accepts a *path-like object*.

The following constants are options for the *flags* parameter to the *open()* function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the *open(2)* manual page on Unix or the MSDN on Windows.

os.**O_RDONLY**

os.**O_WRONLY**

os.**O_RDWR**

os.**O_APPEND**

os.**O_CREAT**

os.**O_EXCL**

os.**O_TRUNC**

The above constants are available on Unix and Windows.

os.**O_DSYNC**

os.**O_RSYNC**

os.**O_SYNC**

os.**O_NDELAY**

os.**O_NONBLOCK**

os.**O_NOCTTY**

os.**O_CLOEXEC**

The above constants are only available on Unix.

Changed in version 3.3: Add *O_CLOEXEC* constant.

os.**O_BINARY**

os.**O_NOINHERIT**

os.**O_SHORT_LIVED**

os.**O_TEMPORARY**

os.**O_RANDOM**

os.**O_SEQUENTIAL**

os.**O_TEXT**

The above constants are only available on Windows.

os.**O_EVTONLY**

os.**O_FSYNC**

os.**O_SYMLINK**

os.**O_NOFOLLOW_ANY**

The above constants are only available on macOS.

Changed in version 3.10: Add *O_EVTONLY*, *O_FSYNC*, *O_SYMLINK* and *O_NOFOLLOW_ANY* constants.

os.**O_ASYNC**

os.**O_DIRECT**

os.**O_DIRECTORY**

os.**O_NOFOLLOW**

os.**O_NOATIME**

os.**O_PATH**

os.**O_TMPFILE**

os.**O_SHLOCK**

os.**O_EXLOCK**

The above constants are extensions and not present if they are not defined by the C library.

Changed in version 3.4: Add *O_PATH* on systems that support it. Add *O_TMPFILE*, only available on Linux Kernel 3.11 or newer.

os.**openpty**()

Open a new pseudo-terminal pair. Return a pair of file descriptors `(master, slave)` for the pty and the tty, respectively. The new file descriptors are *non-inheritable*. For a (slightly) more portable approach, use the *pty* module.

Availability: Unix, not WASI.

Changed in version 3.4: The new file descriptors are now non-inheritable.

os.**pipe**()

Create a pipe. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively. The new file descriptor is *non-inheritable*.

Availability: Unix, Windows.

Changed in version 3.4: The new file descriptors are now non-inheritable.

os.**pipe2**(*flags*, */*)

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: *O_NONBLOCK*, *O_CLOEXEC*. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively.

Availability: Unix, not WASI.

Added in version 3.3.

os.**posix_fallocate**(*fd*, *offset*, *len*, /)

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

Availability: Unix.

Added in version 3.3.

os.**posix_fadvise**(*fd*, *offset*, *len*, *advice*, /)

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The advice applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of *POSIX_FADV_NORMAL*, *POSIX_FADV_SEQUENTIAL*, *POSIX_FADV_RANDOM*, *POSIX_FADV_NOREUSE*, *POSIX_FADV_WILLNEED* or *POSIX_FADV_DONTNEED*.

Availability: Unix.

Added in version 3.3.

os.**POSIX_FADV_NORMAL**

os.**POSIX_FADV_SEQUENTIAL**

os.**POSIX_FADV_RANDOM**

os.**POSIX_FADV_NOREUSE**

os.**POSIX_FADV_WILLNEED**

os.**POSIX_FADV_DONTNEED**

Flags that can be used in *advice* in *posix_fadvise()* that specify the access pattern that is likely to be used.

Availability: Unix.

Added in version 3.3.

os.**pread**(*fd*, *n*, *offset*, /)

Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Availability: Unix.

Added in version 3.3.

os.**posix_openpt**(*oflag*, /)

Open and return a file descriptor for a master pseudo-terminal device.

Calls the C standard library function `posix_openpt()`. The *oflag* argument is used to set file status flags and file access modes as specified in the manual page of `posix_openpt()` of your system.

The returned file descriptor is *non-inheritable*. If the value *O_CLOEXEC* is available on the system, it is added to *oflag*.

Availability: Unix, not WASI.

Added in version 3.13.

os.**preadv**(*fd*, *buffers*, *offset*, *flags=0*, /)

Read from a file descriptor *fd* at a position of *offset* into mutable *bytes-like objects* *buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_HIPRI*
- *RWF_NOWAIT*

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of *os.readv()* and *os.pread()*.

Availability: Linux >= 2.6.30, FreeBSD >= 6.0, OpenBSD >= 2.7, AIX >= 7.1.

Using flags requires Linux >= 4.6.

Added in version 3.7.

`os.`**`RWF_NOWAIT`**

Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set errno to *errno.EAGAIN*.

Availability: Linux >= 4.14.

Added in version 3.7.

`os.`**`RWF_HIPRI`**

High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the *O_DIRECT* flag.

Availability: Linux >= 4.6.

Added in version 3.7.

`os.`**`ptsname`**(*fd*, */*)

Return the name of the slave pseudo-terminal device associated with the master pseudo-terminal device to which the file descriptor *fd* refers. The file descriptor *fd* is not closed upon failure.

Calls the reentrant C standard library function `ptsname_r()` if it is available; otherwise, the C standard library function `ptsname()`, which is not guaranteed to be thread-safe, is called.

Availability: Unix, not WASI.

Added in version 3.13.

`os.`**`pwrite`**(*fd*, *str*, *offset*, */*)

Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

Availability: Unix.

Added in version 3.3.

`os.`**`pwritev`**(*fd*, *buffers*, *offset*, *flags=0*, */*)

Write the *buffers* contents to file descriptor *fd* at an offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_DSYNC*
- *RWF_SYNC*
- *RWF_APPEND*

Return the total number of bytes actually written.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of *os.writev()* and *os.pwrite()*.

Availability: Linux >= 2.6.30, FreeBSD >= 6.0, OpenBSD >= 2.7, AIX >= 7.1.

Using flags requires Linux >= 4.6.

Added in version 3.7.

os.**RWF_DSYNC**

Provide a per-write equivalent of the *O_DSYNC* *os.open()* flag. This flag effect applies only to the data range written by the system call.

Availability: Linux >= 4.7.

Added in version 3.7.

os.**RWF_SYNC**

Provide a per-write equivalent of the *O_SYNC* *os.open()* flag. This flag effect applies only to the data range written by the system call.

Availability: Linux >= 4.7.

Added in version 3.7.

os.**RWF_APPEND**

Provide a per-write equivalent of the *O_APPEND* *os.open()* flag. This flag is meaningful only for *os.pwritev()*, and its effect applies only to the data range written by the system call. The *offset* argument does not affect the write operation; the data is always appended to the end of the file. However, if the *offset* argument is `-1`, the current file *offset* is updated.

Availability: Linux >= 4.16.

Added in version 3.10.

os.**read**(*fd*, *n*, */*)

Read at most *n* bytes from file descriptor *fd*.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

> **Note**
>
> This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To read a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdin*, use its `read()` or `readline()` methods.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**sendfile**(*out_fd*, *in_fd*, *offset*, *count*)

os.**sendfile**(*out_fd*, *in_fd*, *offset*, *count*, *headers=()*, *trailers=()*, *flags=0*)

Copy *count* bytes from file descriptor *in_fd* to file descriptor *out_fd* starting at *offset*. Return the number of bytes sent. When EOF is reached return `0`.

The first function notation is supported by all platforms that define *sendfile()*.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in_fd* and the position of *in_fd* is updated.

The second case may be used on macOS and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in_fd* is written. It returns the same as the first case.

On macOS and FreeBSD, a value of `0` for *count* specifies to send until the end of *in_fd* is reached.

All platforms support sockets as *out_fd* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

Availability: Unix, not WASI.

> **Note**
>
> For a higher-level wrapper of `sendfile()`, see `socket.socket.sendfile()`.

Added in version 3.3.

Changed in version 3.9: Parameters *out* and *in* was renamed to *out_fd* and *in_fd*.

os.SF_NODISKIO

os.SF_MNOWAIT

os.SF_SYNC

Parameters to the `sendfile()` function, if the implementation supports them.

Availability: Unix, not WASI.

Added in version 3.3.

os.SF_NOCACHE

Parameter to the `sendfile()` function, if the implementation supports it. The data won't be cached in the virtual memory and will be freed afterwards.

Availability: Unix, not WASI.

Added in version 3.11.

os.set_blocking(*fd*, *blocking*, /)

Set the blocking mode of the specified file descriptor. Set the `O_NONBLOCK` flag if blocking is `False`, clear the flag otherwise.

See also `get_blocking()` and `socket.socket.setblocking()`.

Availability: Unix, Windows.

The function is limited on WASI, see *WebAssembly platforms* for more information.

On Windows, this function is limited to pipes.

Added in version 3.5.

Changed in version 3.12: Added support for pipes on Windows.

os.splice(*src*, *dst*, *count*, *offset_src=None*, *offset_dst=None*)

Transfer *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. At least one of the file descriptors must refer to a pipe. If *offset_src* is `None`, then *src* is read from the current position; respectively for *offset_dst*. The offset associated to the file descriptor that refers to a pipe must be `None`. The files pointed to by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with `errno` set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

Upon successful completion, returns the number of bytes spliced to or from the pipe. A return value of 0 means end of input. If *src* refers to a pipe, then this means that there was no data to transfer, and it would not make sense to block because there are no writers connected to the write end of the pipe.

Availability: Linux >= 2.6.17 with glibc >= 2.5

Added in version 3.10.

os.**SPLICE_F_MOVE**

os.**SPLICE_F_NONBLOCK**

os.**SPLICE_F_MORE**

Added in version 3.10.

os.**readv**(*fd*, *buffers*, /)

Read from a file descriptor *fd* into a number of mutable *bytes-like objects* *buffers*. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Availability: Unix.

Added in version 3.3.

os.**tcgetpgrp**(*fd*, /)

Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*).

Availability: Unix, not WASI.

os.**tcsetpgrp**(*fd*, *pg*, /)

Set the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*) to *pg*.

Availability: Unix, not WASI.

os.**ttyname**(*fd*, /)

Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

Availability: Unix.

os.**unlockpt**(*fd*, /)

Unlock the slave pseudo-terminal device associated with the master pseudo-terminal device to which the file descriptor *fd* refers. The file descriptor *fd* is not closed upon failure.

Calls the C standard library function `unlockpt()`.

Availability: Unix, not WASI.

Added in version 3.13.

os.**write**(*fd*, *str*, /)

Write the bytestring in *str* to file descriptor *fd*.

Return the number of bytes actually written.

> **Note**
>
> This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To write a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdout* or *sys.stderr*, use its `write()` method.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**writev**(*fd*, *buffers*, /)

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (*sysconf()* value 'SC_IOV_MAX') on the number of buffers that can be used.

Availability: Unix.

Added in version 3.3.

Querying the size of a terminal

Added in version 3.3.

os.**get_terminal_size**(*fd=STDOUT_FILENO*, /)

Return the size of the terminal window as (columns, lines), tuple of type *terminal_size*.

The optional argument fd (default STDOUT_FILENO, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an *OSError* is raised.

shutil.get_terminal_size() is the high-level function which should normally be used, os.get_terminal_size is the low-level implementation.

Availability: Unix, Windows.

class os.**terminal_size**

A subclass of tuple, holding (columns, lines) of the terminal window size.

columns

Width of the terminal window in characters.

lines

Height of the terminal window in characters.

Inheritance of File Descriptors

Added in version 3.4.

A file descriptor has an "inheritable" flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: stdin, stdout and stderr), which are always inherited. Using *spawn** functions, all inheritable handles and all inheritable file descriptors are inherited. Using the *subprocess* module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the *close_fds* parameter is False.

On WebAssembly platforms, the file descriptor cannot be modified.

os.**get_inheritable**(*fd*, /)

Get the "inheritable" flag of the specified file descriptor (a boolean).

os.**set_inheritable**(*fd*, *inheritable*, /)

Set the "inheritable" flag of the specified file descriptor.

os.**get_handle_inheritable**(*handle*, /)

Get the "inheritable" flag of the specified handle (a boolean).

Availability: Windows.

os.**set_handle_inheritable**(*handle*, *inheritable*, /)

Set the "inheritable" flag of the specified handle.

Availability: Windows.

16.1.6 Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** Normally the *path* argument provided to functions in the `os` module must be a string specifying a file path. However, some functions now alternatively accept an open file descriptor for their *path* argument. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the variant of the function prefixed with `f` (e.g. call `fchdir` instead of `chdir`).)

  You can check whether or not *path* can be specified as a file descriptor for a particular function on your platform using `os.supports_fd`. If this functionality is unavailable, using it will raise a `NotImplementedError`.

  If the function also supports *dir_fd* or *follow_symlinks* arguments, it's an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, *dir_fd* is ignored. (For POSIX systems, Python will call the variant of the function with an `at` suffix and possibly prefixed with `f` (e.g. call `faccessat` instead of `access`).

  You can check whether or not *dir_fd* is supported for a particular function on your platform using `os.supports_dir_fd`. If it's unavailable, using it will raise a `NotImplementedError`.

- **not following symlinks:** If *follow_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself rather than the file pointed to by the link. (For POSIX systems, Python will call the `l...` variant of the function.)

  You can check whether or not *follow_symlinks* is supported for a particular function on your platform using `os.supports_follow_symlinks`. If it's unavailable, using it will raise a `NotImplementedError`.

os.**access**(*path*, *mode*, *, *dir_fd=None*, *effective_ids=False*, *follow_symlinks=True*)

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be `F_OK` to test the existence of *path*, or it can be the inclusive OR of one or more of `R_OK`, `W_OK`, and `X_OK` to test permissions. Return `True` if access is allowed, `False` if not. See the Unix man page `access(2)` for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If *effective_ids* is `True`, `access()` will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective_ids* may not be supported on your platform; you can check whether or not it is available using `os.supports_effective_ids`. If it is unavailable, using it will raise a `NotImplementedError`.

> **Note**
>
> Using `access()` to check if a user is authorized to e.g. open a file before actually doing so using `open()` creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:
>
> ```
> if os.access("myfile", os.R_OK):
>     with open("myfile") as fp:
>         return fp.read()
> return "some default data"
> ```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

Note

I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

Changed in version 3.3: Added the *dir_fd*, *effective_ids*, and *follow_symlinks* parameters.

Changed in version 3.6: Accepts a *path-like object*.

os.**F_OK**

os.**R_OK**

os.**W_OK**

os.**X_OK**

Values to pass as the *mode* parameter of `access()` to test the existence, readability, writability and executability of *path*, respectively.

os.**chdir**(*path*)

Change the current working directory to *path*.

This function can support *specifying a file descriptor*. The descriptor must refer to an opened directory, not an open file.

This function can raise `OSError` and subclasses such as `FileNotFoundError`, `PermissionError`, and `NotADirectoryError`.

Raises an *auditing event* `os.chdir` with argument `path`.

Changed in version 3.3: Added support for specifying *path* as a file descriptor on some platforms.

Changed in version 3.6: Accepts a *path-like object*.

os.**chflags**(*path*, *flags*, *, *follow_symlinks=True*)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the `stat` module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`
- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`
- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`

- *stat.SF_APPEND*
- *stat.SF_NOUNLINK*
- *stat.SF_SNAPSHOT*

This function can support *not following symlinks*.

Raises an *auditing event* `os.chflags` with arguments `path`, `flags`.

Availability: Unix, not WASI.

Changed in version 3.3: Added the *follow_symlinks* parameter.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`chmod`**(*path*, *mode*, ***, *dir_fd=None*, *follow_symlinks=True*)

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the *stat* module) or bitwise ORed combinations of them:

- *stat.S_ISUID*
- *stat.S_ISGID*
- *stat.S_ENFMT*
- *stat.S_ISVTX*
- *stat.S_IREAD*
- *stat.S_IWRITE*
- *stat.S_IEXEC*
- *stat.S_IRWXU*
- *stat.S_IRUSR*
- *stat.S_IWUSR*
- *stat.S_IXUSR*
- *stat.S_IRWXG*
- *stat.S_IRGRP*
- *stat.S_IWGRP*
- *stat.S_IXGRP*
- *stat.S_IRWXO*
- *stat.S_IROTH*
- *stat.S_IWOTH*
- *stat.S_IXOTH*

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

Note

Although Windows supports *chmod()*, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored. The default value of *follow_symlinks* is `False` on Windows.

The function is limited on WASI, see *WebAssembly platforms* for more information.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

Changed in version 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.13: Added support for a file descriptor and the *follow_symlinks* argument on Windows.

`os.chown`(*path*, *uid*, *gid*, ***, *dir_fd=None*, *follow_symlinks=True*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

See `shutil.chown()` for a higher-level function that accepts names in addition to numeric ids.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

The function is limited on WASI, see *WebAssembly platforms* for more information.

Changed in version 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Changed in version 3.6: Supports a *path-like object*.

`os.chroot`(*path*)

Change the root directory of the current process to *path*.

Availability: Unix, not WASI, not Android.

Changed in version 3.6: Accepts a *path-like object*.

`os.fchdir`(*fd*)

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

Raises an *auditing event* `os.chdir` with argument `path`.

Availability: Unix.

`os.getcwd`()

Return a string representing the current working directory.

`os.getcwdb`()

Return a bytestring representing the current working directory.

Changed in version 3.8: The function now uses the UTF-8 encoding on Windows, rather than the ANSI code page: see **PEP 529** for the rationale. The function is no longer deprecated on Windows.

`os.lchflags`(*path*, *flags*)

Set the flags of *path* to the numeric *flags*, like `chflags()`, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Raises an *auditing event* `os.chflags` with arguments `path`, `flags`.

Availability: Unix, not WASI.

Changed in version 3.6: Accepts a *path-like object*.

`os.lchmod`(*path*, *mode*)

Change the mode of *path* to the numeric *mode*. If path is a symlink, this affects the symlink rather than the target. See the docs for `chmod()` for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

`lchmod()` is not part of POSIX, but Unix implementations may have it if changing the mode of symbolic links is supported.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

Availability: Unix, Windows, not Linux, FreeBSD >= 1.3, NetBSD >= 1.3, not OpenBSD

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.13: Added support on Windows.

os.lchown(*path*, *uid*, *gid*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

os.link(*src*, *dst*, ***, *src_dir_fd=None*, *dst_dir_fd=None*, *follow_symlinks=True*)

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*, and *not following symlinks*.

Raises an *auditing event* `os.link` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Availability: Unix, Windows.

Changed in version 3.2: Added Windows support.

Changed in version 3.3: Added the *src_dir_fd*, *dst_dir_fd*, and *follow_symlinks* parameters.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

os.listdir(*path='.'*)

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory. If a file is removed from or added to the directory during the call of this function, whether a name for that file be included is unspecified.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Raises an *auditing event* `os.listdir` with argument `path`.

Note

To encode `str` filenames to `bytes`, use *fsencode()*.

See also

The *scandir()* function returns directory entries along with file attribute information, giving better performance for many common use cases.

Changed in version 3.2: The *path* parameter became optional.

Changed in version 3.3: Added support for specifying *path* as an open file descriptor.

Changed in version 3.6: Accepts a *path-like object*.

os.**listdrives**()

Return a list containing the names of drives on a Windows system.

A drive name typically looks like `'C:\\'`. Not every drive name will be associated with a volume, and some may be inaccessible for a variety of reasons, including permissions, network connectivity or missing media. This function does not test for access.

May raise *OSError* if an error occurs collecting the drive names.

Raises an *auditing event* `os.listdrives` with no arguments.

Availability: Windows

Added in version 3.12.

os.**listmounts**(*volume*)

Return a list containing the mount points for a volume on a Windows system.

volume must be represented as a GUID path, like those returned by *os.listvolumes()*. Volumes may be mounted in multiple locations or not at all. In the latter case, the list will be empty. Mount points that are not associated with a volume will not be returned by this function.

The mount points return by this function will be absolute paths, and may be longer than the drive name.

Raises *OSError* if the volume is not recognized or if an error occurs collecting the paths.

Raises an *auditing event* `os.listmounts` with argument `volume`.

Availability: Windows

Added in version 3.12.

os.**listvolumes**()

Return a list containing the volumes in the system.

Volumes are typically represented as a GUID path that looks like `\\?\Volume{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}\`. Files can usually be accessed through a GUID path, permissions allowing. However, users are generally not familiar with them, and so the recommended use of this function is to retrieve mount points using *os.listmounts()*.

May raise *OSError* if an error occurs collecting the volumes.

Raises an *auditing event* `os.listvolumes` with no arguments.

Availability: Windows

Added in version 3.12.

os.**lstat**(*path*, ***, *dir_fd=None*)

Perform the equivalent of an `lstat()` system call on the given path. Similar to *stat()*, but does not follow symbolic links. Return a *stat_result* object.

On platforms that do not support symbolic links, this is an alias for *stat()*.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support *paths relative to directory descriptors*.

See also

The *stat()* function.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.8: On Windows, now opens reparse points that represent another path (name surrogates), including symbolic links and directory junctions. Other kinds of reparse points are resolved by the operating system as for `stat()`.

`os.mkdir`(*path*, *mode=0o777*, ***, *dir_fd=None*)

Create a directory named *path* with numeric mode *mode*.

If the directory already exists, `FileExistsError` is raised. If a parent directory in the path does not exist, `FileNotFoundError` is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

On Windows, a *mode* of `0o700` is specifically handled to apply access control to the new directory such that only the current user and administrators have access. Other values of *mode* are ignored.

This function can also support *paths relative to directory descriptors*.

It is also possible to create temporary directories; see the `tempfile` module's `tempfile.mkdtemp()` function.

Raises an *auditing event* `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.13: Windows now handles a *mode* of `0o700`.

`os.makedirs`(*name*, *mode=0o777*, *exist_ok=False*)

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory.

The *mode* parameter is passed to `mkdir()` for creating the leaf directory; see *the mkdir() description* for how it is interpreted. To set the file permission bits of any newly created parent directories you can set the umask before invoking `makedirs()`. The file permission bits of existing parent directories are not changed.

If *exist_ok* is `False` (the default), a `FileExistsError` is raised if the target directory already exists.

> **Note**
>
> `makedirs()` will become confused if the path elements to create include `pardir` (eg. ".." on UNIX systems).

This function handles UNC paths correctly.

Raises an *auditing event* `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

Changed in version 3.2: Added the *exist_ok* parameter.

Changed in version 3.4.1: Before Python 3.4.1, if *exist_ok* was `True` and the directory existed, `makedirs()` would still raise an error if *mode* did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See bpo-21082.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.7: The *mode* argument no longer affects the file permission bits of newly created intermediate-level directories.

`os.mkfifo`(*path*, *mode=0o666*, ***, *dir_fd=None*)

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support *paths relative to directory descriptors*.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with *os.unlink()*). Generally, FIFOs are used as rendezvous between "client" and "server" type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that *mkfifo()* doesn't open the FIFO — it just creates the rendezvous point.

Availability: Unix, not WASI.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`mknod`**(*path*, *mode=0o600*, *device=0*, ***, *dir_fd=None*)

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in *stat*). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using *os.makedev()*), otherwise it is ignored.

This function can also support *paths relative to directory descriptors*.

Availability: Unix, not WASI.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`major`**(*device*, */*)

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.`**`minor`**(*device*, */*)

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.`**`makedev`**(*major*, *minor*, */*)

Compose a raw device number from the major and minor device numbers.

`os.`**`pathconf`**(*path*, *name*)

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

This function can support *specifying a file descriptor*.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`pathconf_names`**

Dictionary mapping names accepted by *pathconf()* and *fpathconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

`os.`**`readlink`**(*path*, ***, *dir_fd=None*)

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a `PathLike` interface), the result will also be a string object, and the call may raise a UnicodeDecodeError. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support *paths relative to directory descriptors*.

When trying to resolve a path that may contain links, use `realpath()` to properly handle recursion and platform differences.

Availability: Unix, Windows.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object* on Unix.

Changed in version 3.8: Accepts a *path-like object* and a bytes object on Windows.

Added support for directory junctions, and changed to return the substitution path (which typically includes `\\?\` prefix) rather than the optional "print name" field that was previously returned.

`os.`**`remove`**(*path*, *, *dir_fd=None*)

Remove (delete) the file *path*. If *path* is a directory, an `OSError` is raised. Use `rmdir()` to remove directories. If the file does not exist, a `FileNotFoundError` is raised.

This function can support *paths relative to directory descriptors*.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to `unlink()`.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`removedirs`**(*name*)

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises `OSError` if the leaf directory could not be successfully removed.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`rename`**(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* exists, the operation will fail with an `OSError` subclass in a number of cases:

On Windows, if *dst* exists a `FileExistsError` is always raised. The operation may fail if *src* and *dst* are on different filesystems. Use `shutil.move()` to support moves to a different filesystem.

On Unix, if *src* is a file and *dst* is a directory or vice-versa, an `IsADirectoryError` or a `NotADirectoryError` will be raised respectively. If both are directories and *dst* is empty, *dst* will be silently replaced. If *dst* is a non-empty directory, an `OSError` is raised. If both are files, *dst* will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

If you want cross-platform overwriting of the destination, use `replace()`.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Changed in version 3.3: Added the *src_dir_fd* and *dst_dir_fd* parameters.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

`os.renames`(*old*, *new*)

Recursive directory or file renaming function. Works like `rename()`, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using `removedirs()`.

Note

This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Changed in version 3.6: Accepts a *path-like object* for *old* and *new*.

`os.replace`(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* is a non-empty directory, `OSError` will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Added in version 3.3.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

`os.rmdir`(*path*, *, *dir_fd=None*)

Remove (delete) the directory *path*. If the directory does not exist or is not empty, a `FileNotFoundError` or an `OSError` is raised respectively. In order to remove whole directory trees, `shutil.rmtree()` can be used.

This function can support *paths relative to directory descriptors*.

Raises an *auditing event* `os.rmdir` with arguments `path`, `dir_fd`.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

`os.scandir`(*path='.'*)

Return an iterator of `os.DirEntry` objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether an entry for that file be included is unspecified.

Using `scandir()` instead of `listdir()` can significantly increase the performance of code that also needs file type or file attribute information, because `os.DirEntry` objects expose this information if the operating system provides it when scanning a directory. All `os.DirEntry` methods may perform a system call, but `is_dir()` and `is_file()` usually only require a system call for symbolic links; `os.DirEntry.stat()` always requires a system call on Unix but only requires one for symbolic links on Windows.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the `PathLike` interface), the type of the `name` and `path` attributes of each `os.DirEntry` will be `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Raises an *auditing event* `os.scandir` with argument `path`.

The *scandir()* iterator supports the *context manager* protocol and has the following method:

scandir.**close**()

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the `with` statement.

Added in version 3.6.

The following example shows a simple use of *scandir()* to display all the files (excluding directories) in the given *path* that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

Note

On Unix-based systems, *scandir()* uses the system's opendir() and readdir() functions. On Windows, it uses the Win32 FindFirstFileW and FindNextFileW functions.

Added in version 3.5.

Changed in version 3.6: Added support for the *context manager* protocol and the *close()* method. If a *scandir()* iterator is neither exhausted nor explicitly closed a *ResourceWarning* will be emitted in its destructor.

The function accepts a *path-like object*.

Changed in version 3.7: Added support for *file descriptors* on Unix.

class os.**DirEntry**

Object yielded by *scandir()* to expose the file path and other file attributes of a directory entry.

scandir() will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling *scandir()*, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise *OSError*. If you need very fine-grained control over errors, you can catch *OSError* when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a *path-like object*, `os.DirEntry` implements the *PathLike* interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

name

The entry's base filename, relative to the *scandir()* *path* argument.

The *name* attribute will be `bytes` if the *scandir()* *path* argument is of type `bytes` and `str` otherwise. Use *fsdecode()* to decode byte filenames.

path

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where *scandir_path* is the *scandir()* *path* argument. The path is only absolute if the *scandir()* *path* argument was absolute. If the *scandir()* *path* argument was a *file descriptor*, the *path* attribute is the same as the *name* attribute.

The *path* attribute will be `bytes` if the *scandir()* *path* argument is of type `bytes` and `str` otherwise. Use *fsdecode()* to decode byte filenames.

inode()

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

is_dir(*, *follow_symlinks=True*)

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call *os.stat()* along with *stat.S_ISDIR()* to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless *follow_symlinks* is `False`.

This method can raise *OSError*, such as *PermissionError*, but *FileNotFoundError* is caught and not raised.

is_file(*, *follow_symlinks=True*)

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per *is_dir()*.

is_symlink()

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call *os.path.islink()* to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise *OSError*, such as *PermissionError*, but *FileNotFoundError* is caught and not raised.

is_junction()

Return `True` if this entry is a junction (even if broken); return `False` if the entry points to a regular directory, any kind of file, a symlink, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call *os.path.isjunction()* to fetch up-to-date information.

Added in version 3.12.

stat(*, *follow_symlinks=True*)

Return a *stat_result* object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if *follow_symlinks* is `True` and the entry is a reparse point (for example, a symbolic link or directory junction).

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the *stat_result* are always set to zero. Call *os.stat()* to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call *os.stat()* to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of *pathlib.Path*. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()`, `is_junction()`, and `stat()` methods.

Added in version 3.5.

Changed in version 3.6: Added support for the *PathLike* interface. Added support for *bytes* paths on Windows.

Changed in version 3.12: The `st_ctime` attribute of a stat result is deprecated on Windows. The file creation time is properly available as `st_birthtime`, and in the future `st_ctime` may be changed to return zero or the metadata change time, if available.

`os.`**`stat`**(*path*, ***, *dir_fd=None*, *follow_symlinks=True*)

Get the status of a file or a file descriptor. Perform the equivalent of a `stat()` system call on the given path. *path* may be specified as either a string or bytes – directly or indirectly through the *PathLike* interface – or as an open file descriptor. Return a *stat_result* object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use *lstat()*.

This function can support *specifying a file descriptor* and *not following symlinks*.

On Windows, passing `follow_symlinks=False` will disable following all name-surrogate reparse points, which includes symlinks and directory junctions. Other types of reparse points that do not resemble links or that the operating system is unable to follow will be opened directly. When following a chain of multiple links, this may result in the original link being returned instead of the non-link that prevented full traversal. To obtain stat results for the final path in this case, use the *os.path.realpath()* function to resolve the path name as far as possible and call *lstat()* on the result. This does not apply to dangling symlinks or junction points, which will raise the usual exceptions.

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=234881026,
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_atime=1297230295,
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

See also

fstat() and *lstat()* functions.

Changed in version 3.3: Added the *dir_fd* and *follow_symlinks* parameters, specifying a file descriptor instead of a path.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.8: On Windows, all reparse points that can be resolved by the operating system are now followed, and passing `follow_symlinks=False` disables following all name surrogate reparse points. If the

operating system reaches a reparse point that it is not able to follow, *stat* now returns the information for the original path as if `follow_symlinks=False` had been specified instead of raising an error.

class os.**stat_result**

Object whose attributes correspond roughly to the members of the `stat` structure. It is used for the result of *os.stat()*, *os.fstat()* and *os.lstat()*.

Attributes:

st_mode

File mode: file type and file mode bits (permissions).

st_ino

Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the file index on Windows

st_dev

Identifier of the device on which this file resides.

st_nlink

Number of hard links.

st_uid

User identifier of the file owner.

st_gid

Group identifier of the file owner.

st_size

Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

st_atime

Time of most recent access expressed in seconds.

st_mtime

Time of most recent content modification expressed in seconds.

st_ctime

Time of most recent metadata change expressed in seconds.

Changed in version 3.12: `st_ctime` is deprecated on Windows. Use `st_birthtime` for the file creation time. In the future, `st_ctime` will contain the time of the most recent metadata change, as for other platforms.

st_atime_ns

Time of most recent access expressed in nanoseconds as an integer.

Added in version 3.3.

st_mtime_ns

Time of most recent content modification expressed in nanoseconds as an integer.

Added in version 3.3.

st_ctime_ns

Time of most recent metadata change expressed in nanoseconds as an integer.

Added in version 3.3.

Changed in version 3.12: `st_ctime_ns` is deprecated on Windows. Use `st_birthtime_ns` for the file creation time. In the future, `st_ctime` will contain the time of the most recent metadata change, as for other platforms.

st_birthtime

Time of file creation expressed in seconds. This attribute is not always available, and may raise *AttributeError*.

Changed in version 3.12: `st_birthtime` is now available on Windows.

st_birthtime_ns

Time of file creation expressed in nanoseconds as an integer. This attribute is not always available, and may raise *AttributeError*.

Added in version 3.12.

Note

The exact meaning and resolution of the *st_atime*, *st_mtime*, *st_ctime* and *st_birthtime* attributes depend on the operating system and the file system. For example, on Windows systems using the FAT32 file systems, *st_mtime* has 2-second resolution, and *st_atime* has only 1-day resolution. See your operating system documentation for details.

Similarly, although *st_atime_ns*, *st_mtime_ns*, *st_ctime_ns* and *st_birthtime_ns* are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store *st_atime*, *st_mtime*, *st_ctime* and *st_birthtime* cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use *st_atime_ns*, *st_mtime_ns*, *st_ctime_ns* and *st_birthtime_ns*.

On some Unix systems (such as Linux), the following attributes may also be available:

st_blocks

Number of 512-byte blocks allocated for file. This may be smaller than *st_size*/512 when the file has holes.

st_blksize

"Preferred" blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

st_rdev

Type of device if an inode device.

st_flags

User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

st_gen

File generation number.

On Solaris and derivatives, the following attributes may also be available:

st_fstype

String that uniquely identifies the type of the filesystem that contains the file.

On macOS systems, the following attributes may also be available:

st_rsize

Real size of the file.

st_creator

Creator of the file.

st_type

File type.

On Windows systems, the following attributes are also available:

st_file_attributes

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_* <stat.FILE_ATTRIBUTE_ARCHIVE>` constants in the *stat* module.

Added in version 3.5.

st_reparse_tag

When *st_file_attributes* has the *FILE_ATTRIBUTE_REPARSE_POINT* set, this field contains the tag identifying the type of reparse point. See the *IO_REPARSE_TAG_** constants in the *stat* module.

The standard module *stat* defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a *stat_result* instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order *st_mode*, *st_ino*, *st_dev*, *st_nlink*, *st_uid*, *st_gid*, *st_size*, *st_atime*, *st_mtime*, *st_ctime*. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing *stat_result* as a tuple always returns integers.

Changed in version 3.5: Windows now returns the file index as *st_ino* when available.

Changed in version 3.7: Added the *st_fstype* member to Solaris/derivatives.

Changed in version 3.8: Added the *st_reparse_tag* member on Windows.

Changed in version 3.8: On Windows, the *st_mode* member now identifies special files as `S_IFCHR`, `S_IFIFO` or `S_IFBLK` as appropriate.

Changed in version 3.12: On Windows, *st_ctime* is deprecated. Eventually, it will contain the last metadata change time, for consistency with other platforms, but for now still contains creation time. Use *st_birthtime* for the creation time.

On Windows, *st_ino* may now be up to 128 bits, depending on the file system. Previously it would not be above 64 bits, and larger file identifiers would be arbitrarily packed.

On Windows, *st_rdev* no longer returns a value. Previously it would contain the same as *st_dev*, which was incorrect.

Added the *st_birthtime* member on Windows.

`os.`**statvfs**(*path*)

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`, `f_fsid`.

Two module-level constants are defined for the `f_flag` attribute's bit-flags: if `ST_RDONLY` is set, the filesystem is mounted read-only, and if `ST_NOSUID` is set, the semantics of setuid/setgid bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are `ST_NODEV` (disallow access to device special files), `ST_NOEXEC` (disallow program execution), `ST_SYNCHRONOUS` (writes are synced at once), `ST_MANDLOCK` (allow mandatory locks on an FS), `ST_WRITE` (write on file/directory/symlink), `ST_APPEND` (append-only file), `ST_IMMUTABLE` (immutable file), `ST_NOATIME` (do not update access times), `ST_NODIRATIME` (do not update directory access times), `ST_RELATIME` (update atime relative to mtime/ctime).

This function can support *specifying a file descriptor*.

Availability: Unix.

Changed in version 3.2: The `ST_RDONLY` and `ST_NOSUID` constants were added.

Changed in version 3.3: Added support for specifying *path* as an open file descriptor.

Changed in version 3.4: The `ST_NODEV`, `ST_NOEXEC`, `ST_SYNCHRONOUS`, `ST_MANDLOCK`, `ST_WRITE`, `ST_APPEND`, `ST_IMMUTABLE`, `ST_NOATIME`, `ST_NODIRATIME`, and `ST_RELATIME` constants were added.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.7: Added the `f_fsid` attribute.

os.**supports_dir_fd**

A *set* object indicating which functions in the *os* module accept an open file descriptor for their *dir_fd* parameter. Different platforms provide different features, and the underlying functionality Python uses to implement the *dir_fd* parameter is not available on all platforms Python supports. For consistency's sake, functions that may support *dir_fd* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `None` for *dir_fd* is always supported on all platforms.)

To check whether a particular function accepts an open file descriptor for its *dir_fd* parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression evaluates to `True` if *os.stat()* accepts open file descriptors for *dir_fd* on the local platform:

```
os.stat in os.supports_dir_fd
```

Currently *dir_fd* parameters only work on Unix platforms; none of them work on Windows.

Added in version 3.3.

os.**supports_effective_ids**

A *set* object indicating whether *os.access()* permits specifying `True` for its *effective_ids* parameter on the local platform. (Specifying `False` for *effective_ids* is always supported on all platforms.) If the local platform supports it, the collection will contain *os.access()*; otherwise it will be empty.

This expression evaluates to `True` if *os.access()* supports `effective_ids=True` on the local platform:

```
os.access in os.supports_effective_ids
```

Currently *effective_ids* is only supported on Unix platforms; it does not work on Windows.

Added in version 3.3.

os.**supports_fd**

A *set* object indicating which functions in the *os* module permit specifying their *path* parameter as an open file descriptor on the local platform. Different platforms provide different features, and the underlying functionality Python uses to accept open file descriptors as *path* arguments is not available on all platforms Python supports.

To determine whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression evaluates to `True` if *os.chdir()* accepts open file descriptors for *path* on your local platform:

```
os.chdir in os.supports_fd
```

Added in version 3.3.

os.**supports_follow_symlinks**

A *set* object indicating which functions in the *os* module accept `False` for their *follow_symlinks* parameter on the local platform. Different platforms provide different features, and the underlying functionality Python uses to implement *follow_symlinks* is not available on all platforms Python supports. For consistency's sake, functions that may support *follow_symlinks* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `True` for *follow_symlinks* is always supported on all platforms.)

To check whether a particular function accepts `False` for its *follow_symlinks* parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression evaluates to `True` if you may specify `follow_symlinks=False` when calling *os.stat()* on the local platform:

```
os.stat in os.supports_follow_symlinks
```

Added in version 3.3.

os.**symlink**(*src*, *dst*, *target_is_directory=False*, ***, *dir_fd=None*)

Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target_is_directory* is `True` or a file symlink (the default) otherwise. On non-Windows platforms, *target_is_directory* is ignored.

This function can support *paths relative to directory descriptors*.

Note

On newer versions of Windows 10, unprivileged accounts can create symlinks if Developer Mode is enabled. When Developer Mode is not available/enabled, the *SeCreateSymbolicLinkPrivilege* privilege is required, or the process must be run as an administrator.

OSError is raised when the function is called by an unprivileged user.

Raises an *auditing event* `os.symlink` with arguments `src`, `dst`, `dir_fd`.

Availability: Unix, Windows.

The function is limited on WASI, see *WebAssembly platforms* for more information.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Changed in version 3.3: Added the *dir_fd* parameter, and now allow *target_is_directory* on non-Windows platforms.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

Changed in version 3.8: Added support for unelevated symlinks on Windows with Developer Mode.

os.**sync**()

Force write of everything to disk.

Availability: Unix.

Added in version 3.3.

os.**truncate**(*path*, *length*)

Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support *specifying a file descriptor*.

Raises an *auditing event* `os.truncate` with arguments `path`, `length`.

Availability: Unix, Windows.

Added in version 3.3.

Changed in version 3.5: Added support for Windows

Changed in version 3.6: Accepts a *path-like object*.

os.**unlink**(*path*, ***, *dir_fd=None*)

Remove (delete) the file *path*. This function is semantically identical to *remove()*; the `unlink` name is its traditional Unix name. Please see the documentation for *remove()* for further information.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

os.**utime**(*path*, *times=None*, *, [*ns*,]*dir_fd=None*, *follow_symlinks=True*)

Set the access and modified times of the file specified by *path*.

utime() takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Note that the exact times you set here may not be returned by a subsequent *stat()* call, depending on the resolution with which your operating system records access and modification times; see *stat()*. The best way to preserve exact times is to use the *st_atime_ns* and *st_mtime_ns* fields from the *os.stat()* result object with the *ns* parameter to *utime()*.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

Raises an *auditing event* `os.utime` with arguments `path`, `times`, `ns`, `dir_fd`.

Changed in version 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd*, *follow_symlinks*, and *ns* parameters.

Changed in version 3.6: Accepts a *path-like object*.

os.**walk**(*top*, *topdown=True*, *onerror=None*, *followlinks=False*)

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (including symlinks to directories, and excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`. Whether or not the lists are sorted depends on the file system. If a file is removed from or added to the *dirpath* directory during generating the lists, whether a name for that file be included is unspecified.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using `del` or slice assignment), and *walk()* will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform *walk()* about directories the caller creates or renames before it resumes *walk()* again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the *scandir()* call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an *OSError* instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, *walk()* will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

Note

Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. *walk()* does not keep track of the directories it visited already.

Note

If you pass a relative pathname, don't change the current working directory between resumptions of *walk()*. *walk()* never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any `__pycache__` subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/xml'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if '__pycache__' in dirs:
        dirs.remove('__pycache__')  # don't visit __pycache__ directories
```

In the next example (simple implementation of *shutil.rmtree()*), walking the tree bottom-up is essential, *rmdir()* doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
os.rmdir(top)
```

Raises an *auditing event* `os.walk` with arguments `top`, `topdown`, `onerror`, `followlinks`.

Changed in version 3.5: This function now calls *os.scandir()* instead of *os.listdir()*, making it faster by reducing the number of calls to *os.stat()*.

Changed in version 3.6: Accepts a *path-like object*.

`os.`**`fwalk`**(*top='.'*, *topdown=True*, *onerror=None*, ***, *follow_symlinks=False*, *dir_fd=None*)

This behaves exactly like *walk()*, except that it yields a 4-tuple `(dirpath, dirnames, filenames, dirfd)`, and it supports `dir_fd`.

dirpath, *dirnames* and *filenames* are identical to *walk()* output, and *dirfd* is a file descriptor referring to the directory *dirpath*.

This function always supports *paths relative to directory descriptors* and *not following symlinks*. Note however that, unlike other functions, the *fwalk()* default value for *follow_symlinks* is `False`.

Note

Since *fwalk()* yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with *dup()*) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any __pycache__ subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/Lib/xml'):
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size for name in files]),
          end="")
    print("bytes in", len(files), "non-directory files")
    if '__pycache__' in dirs:
        dirs.remove('__pycache__')  # don't visit __pycache__ directories
```

In the next example, walking the tree bottom-up is essential: *rmdir()* doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topdown=False):
    for name in files:
        os.unlink(name, dir_fd=rootfd)
    for name in dirs:
        os.rmdir(name, dir_fd=rootfd)
```

Raises an *auditing event* `os.fwalk` with arguments `top`, `topdown`, `onerror`, `follow_symlinks`, `dir_fd`.

Availability: Unix.

Added in version 3.3.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.7: Added support for *bytes* paths.

os.memfd_create(*name*[, *flags=os.MFD_CLOEXEC*])

Create an anonymous file and return a file descriptor that refers to it. *flags* must be one of the `os.MFD_*` constants available on the system (or a bitwise ORed combination of them). By default, the new file descriptor is *non-inheritable*.

The name supplied in *name* is used as a filename and will be displayed as the target of the corresponding symbolic link in the directory `/proc/self/fd/`. The displayed name is always prefixed with `memfd:` and serves only for debugging purposes. Names do not affect the behavior of the file descriptor, and as such multiple files can have the same name without any side effects.

Availability: Linux >= 3.17 with glibc >= 2.27.

Added in version 3.8.

os.MFD_CLOEXEC

os.MFD_ALLOW_SEALING

os.MFD_HUGETLB

os.MFD_HUGE_SHIFT

os.MFD_HUGE_MASK

os.MFD_HUGE_64KB

os.MFD_HUGE_512KB

os.**MFD_HUGE_1MB**

os.**MFD_HUGE_2MB**

os.**MFD_HUGE_8MB**

os.**MFD_HUGE_16MB**

os.**MFD_HUGE_32MB**

os.**MFD_HUGE_256MB**

os.**MFD_HUGE_512MB**

os.**MFD_HUGE_1GB**

os.**MFD_HUGE_2GB**

os.**MFD_HUGE_16GB**

These flags can be passed to *memfd_create()*.

Availability: Linux >= 3.17 with glibc >= 2.27

The MFD_HUGE* flags are only available since Linux 4.14.

Added in version 3.8.

os.**eventfd**(*initval*[, *flags=os.EFD_CLOEXEC*])

Create and return an event file descriptor. The file descriptors supports raw *read()* and *write()* with a buffer size of 8, *select()*, *poll()* and similar. See man page *eventfd(2)* for more information. By default, the new file descriptor is *non-inheritable*.

initval is the initial value of the event counter. The initial value must be a 32 bit unsigned integer. Please note that the initial value is limited to a 32 bit unsigned int although the event counter is an unsigned 64 bit integer with a maximum value of 2^{64}-2.

flags can be constructed from *EFD_CLOEXEC*, *EFD_NONBLOCK*, and *EFD_SEMAPHORE*.

If *EFD_SEMAPHORE* is specified and the event counter is non-zero, *eventfd_read()* returns 1 and decrements the counter by one.

If *EFD_SEMAPHORE* is not specified and the event counter is non-zero, *eventfd_read()* returns the current event counter value and resets the counter to zero.

If the event counter is zero and *EFD_NONBLOCK* is not specified, *eventfd_read()* blocks.

eventfd_write() increments the event counter. Write blocks if the write operation would increment the counter to a value larger than 2^{64}-2.

Example:

```
import os

# semaphore with start value '1'
fd = os.eventfd(1, os.EFD_SEMAPHORE | os.EFC_CLOEXEC)
try:
    # acquire semaphore
    v = os.eventfd_read(fd)
    try:
        do_work()
    finally:
        # release semaphore
        os.eventfd_write(fd, v)
finally:
    os.close(fd)
```

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.10.

os.**eventfd_read**(*fd*)

Read value from an *eventfd()* file descriptor and return a 64 bit unsigned int. The function does not verify that *fd* is an *eventfd()*.

Availability: Linux >= 2.6.27

Added in version 3.10.

os.**eventfd_write**(*fd*, *value*)

Add value to an *eventfd()* file descriptor. *value* must be a 64 bit unsigned int. The function does not verify that *fd* is an *eventfd()*.

Availability: Linux >= 2.6.27

Added in version 3.10.

os.**EFD_CLOEXEC**

Set close-on-exec flag for new *eventfd()* file descriptor.

Availability: Linux >= 2.6.27

Added in version 3.10.

os.**EFD_NONBLOCK**

Set *O_NONBLOCK* status flag for new *eventfd()* file descriptor.

Availability: Linux >= 2.6.27

Added in version 3.10.

os.**EFD_SEMAPHORE**

Provide semaphore-like semantics for reads from an *eventfd()* file descriptor. On read the internal counter is decremented by one.

Availability: Linux >= 2.6.30

Added in version 3.10.

Timer File Descriptors

Added in version 3.13.

These functions provide support for Linux's *timer file descriptor* API. Naturally, they are all only available on Linux.

os.**timerfd_create**(*clockid*, */*, ***, *flags=0*)

Create and return a timer file descriptor (*timerfd*).

The file descriptor returned by *timerfd_create()* supports:

- *read()*
- *select()*
- *poll()*

The file descriptor's *read()* method can be called with a buffer size of 8. If the timer has already expired one or more times, *read()* returns the number of expirations with the host's endianness, which may be converted to an *int* by `int.from_bytes(x, byteorder=sys.byteorder)`.

select() and *poll()* can be used to wait until timer expires and the file descriptor is readable.

clockid must be a valid *clock ID*, as defined in the *time* module:

- *time.CLOCK_REALTIME*
- *time.CLOCK_MONOTONIC*
- *time.CLOCK_BOOTTIME* (Since Linux 3.15 for timerfd_create)

If *clockid* is *time.CLOCK_REALTIME*, a settable system-wide real-time clock is used. If system clock is changed, timer setting need to be updated. To cancel timer when system clock is changed, see *TFD_TIMER_CANCEL_ON_SET*.

If *clockid* is *time.CLOCK_MONOTONIC*, a non-settable monotonically increasing clock is used. Even if the system clock is changed, the timer setting will not be affected.

If *clockid* is *time.CLOCK_BOOTTIME*, same as *time.CLOCK_MONOTONIC* except it includes any time that the system is suspended.

The file descriptor's behaviour can be modified by specifying a *flags* value. Any of the following variables may used, combined using bitwise OR (the | operator):

- *TFD_NONBLOCK*
- *TFD_CLOEXEC*

If *TFD_NONBLOCK* is not set as a flag, *read()* blocks until the timer expires. If it is set as a flag, *read()* doesn't block, but If there hasn't been an expiration since the last call to read, *read()* raises *OSError* with `errno` is set to *errno.EAGAIN*.

TFD_CLOEXEC is always set by Python automatically.

The file descriptor must be closed with *os.close()* when it is no longer needed, or else the file descriptor will be leaked.

See also

The *timerfd_create(2)* man page.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

`os.`**`timerfd_settime`**(*fd*, /, *, *flags=flags*, *initial=0.0*, *interval=0.0*)

Alter a timer file descriptor's internal timer. This function operates the same interval timer as *timerfd_settime_ns()*.

fd must be a valid timer file descriptor.

The timer's behaviour can be modified by specifying a *flags* value. Any of the following variables may used, combined using bitwise OR (the | operator):

- *TFD_TIMER_ABSTIME*
- *TFD_TIMER_CANCEL_ON_SET*

The timer is disabled by setting *initial* to zero (`0`). If *initial* is equal to or greater than zero, the timer is enabled. If *initial* is less than zero, it raises an *OSError* exception with `errno` set to *errno.EINVAL*

By default the timer will fire when *initial* seconds have elapsed. (If *initial* is zero, timer will fire immediately.)

However, if the *TFD_TIMER_ABSTIME* flag is set, the timer will fire when the timer's clock (set by *clockid* in *timerfd_create()*) reaches *initial* seconds.

The timer's interval is set by the *interval* *float*. If *interval* is zero, the timer only fires once, on the initial expiration. If *interval* is greater than zero, the timer fires every time *interval* seconds have elapsed since the previous expiration. If *interval* is less than zero, it raises *OSError* with `errno` set to *errno.EINVAL*

If the *TFD_TIMER_CANCEL_ON_SET* flag is set along with *TFD_TIMER_ABSTIME* and the clock for this timer is *time.CLOCK_REALTIME*, the timer is marked as cancelable if the real-time clock is changed discontinuously. Reading the descriptor is aborted with the error ECANCELED.

Linux manages system clock as UTC. A daylight-savings time transition is done by changing time offset only and doesn't cause discontinuous system clock change.

Discontinuous system clock change will be caused by the following events:

- `settimeofday`
- `clock_settime`
- set the system date and time by `date` command

Return a two-item tuple of (`next_expiration`, `interval`) from the previous timer state, before this function executed.

See also

timerfd_create(2), *timerfd_settime(2)*, *settimeofday(2)*, *clock_settime(2)*, and *date(1)*.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

`os.`**`timerfd_settime_ns`**(*fd*, /, *, *flags=0*, *initial=0*, *interval=0*)

Similar to *timerfd_settime()*, but use time as nanoseconds. This function operates the same interval timer as *timerfd_settime()*.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

`os.`**`timerfd_gettime`**(*fd*, /)

Return a two-item tuple of floats (`next_expiration`, `interval`).

`next_expiration` denotes the relative time until next the timer next fires, regardless of if the *TFD_TIMER_ABSTIME* flag is set.

`interval` denotes the timer's interval. If zero, the timer will only fire once, after `next_expiration` seconds have elapsed.

See also

timerfd_gettime(2)

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

`os.`**`timerfd_gettime_ns`**(*fd*, /)

Similar to *timerfd_gettime()*, but return time as nanoseconds.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

`os.`**`TFD_NONBLOCK`**

A flag for the *timerfd_create()* function, which sets the *O_NONBLOCK* status flag for the new timer file descriptor. If *TFD_NONBLOCK* is not set as a flag, *read()* blocks.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

`os.`**`TFD_CLOEXEC`**

A flag for the *timerfd_create()* function, If *TFD_CLOEXEC* is set as a flag, set close-on-exec flag for new file descriptor.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

os.**TFD_TIMER_ABSTIME**

A flag for the *timerfd_settime()* and *timerfd_settime_ns()* functions. If this flag is set, *initial* is interpreted as an absolute value on the timer's clock (in UTC seconds or nanoseconds since the Unix Epoch).

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

os.**TFD_TIMER_CANCEL_ON_SET**

A flag for the *timerfd_settime()* and *timerfd_settime_ns()* functions along with *TFD_TIMER_ABSTIME*. The timer is cancelled when the time of the underlying clock changes discontinuously.

Availability: Linux >= 2.6.27 with glibc >= 2.8

Added in version 3.13.

Linux extended attributes

Added in version 3.3.

These functions are all available on Linux only.

os.**getxattr**(*path*, *attribute*, *, *follow_symlinks=True*)

Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly through the *PathLike* interface). If it is str, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* `os.getxattr` with arguments `path`, `attribute`.

Changed in version 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.**listxattr**(*path=None*, *, *follow_symlinks=True*)

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is `None`, *listxattr()* will examine the current directory.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* `os.listxattr` with argument `path`.

Changed in version 3.6: Accepts a *path-like object*.

os.**removexattr**(*path*, *attribute*, *, *follow_symlinks=True*)

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the *PathLike* interface). If it is a string, it is encoded with the *filesystem encoding and error handler*.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* `os.removexattr` with arguments `path`, `attribute`.

Changed in version 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.**setxattr**(*path*, *attribute*, *value*, *flags=0*, *, *follow_symlinks=True*)

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the *PathLike* interface). If it is a str, it is encoded with the *filesystem encoding and error handler*. *flags* may be *XATTR_REPLACE* or *XATTR_CREATE*. If *XATTR_REPLACE* is given and the attribute does not exist, `ENODATA` will be raised. If *XATTR_CREATE* is given and the attribute already exists, the attribute will not be created and `EEXISTS` will be raised.

This function can support *specifying a file descriptor* and *not following symlinks*.

> **Note**
>
> A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

Raises an *auditing event* `os.setxattr` with arguments `path`, `attribute`, `value`, `flags`.

Changed in version 3.6: Accepts a *path-like object* for *path* and *attribute*.

`os.XATTR_SIZE_MAX`

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

`os.XATTR_CREATE`

This is a possible value for the flags argument in *setxattr()*. It indicates the operation must create an attribute.

`os.XATTR_REPLACE`

This is a possible value for the flags argument in *setxattr()*. It indicates the operation must replace an existing attribute.

16.1.7 Process Management

These functions may be used to create and manage processes.

The various *exec** functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

`os.abort()`

Generate a `SIGABRT` signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of `3`. Be aware that calling this function will not call the Python signal handler registered for `SIGABRT` with *signal.signal()*.

`os.add_dll_directory(`*path*`)`

Add a path to the DLL search path.

This search path is used when resolving dependencies for imported extension modules (the module itself is resolved through *sys.path*), and also by *ctypes*.

Remove the directory by calling **close()** on the returned object or using it in a `with` statement.

See the Microsoft documentation for more information about how DLLs are loaded.

Raises an *auditing event* `os.add_dll_directory` with argument `path`.

Availability: Windows.

Added in version 3.8: Previous versions of CPython would resolve DLLs using the default behavior for the current process. This led to inconsistencies, such as only sometimes searching `PATH` or the current working directory, and OS functions such as `AddDllDirectory` having no effect.

In 3.8, the two primary ways DLLs are loaded now explicitly override the process-wide behavior to ensure consistency. See the porting notes for information on updating libraries.

`os.execl(`*path*, *arg0*, *arg1*, ...`)`

`os.execle(`*path*, *arg0*, *arg1*, ..., *env*`)`

`os.execlp(`*file*, *arg0*, *arg1*, ...`)`

`os.execlpe(`*file*, *arg0*, *arg1*, ..., *env*`)`

`os.execv(`*path*, *args*`)`

`os.execve(`*path*, *args*, *env*`)`

`os.execvp(`*file*, *args*`)`

`os.execvpe(`*file*, *args*, *env*`)`

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as *OSError* exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using `sys.stdout.flush()` or *os.fsync()* before calling an *exec** function.

The "l" and "v" variants of the *exec** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `execl*()` functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a "p" near the end (*execlp()*, *execlpe()*, *execvp()*, and *execvpe()*) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the *exec*e* variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, *execl()*, *execle()*, *execv()*, and *execve()*, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path. Relative paths must include at least one slash, even on Windows, as plain names will not be resolved.

For *execle()*, *execlpe()*, *execve()*, and *execvpe()* (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process' environment); the functions *execl()*, *execlp()*, *execv()*, and *execvp()* all cause the new process to inherit the environment of the current process.

For *execve()* on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using *os.supports_fd*. If it is unavailable, using it will raise a *NotImplementedError*.

Raises an *auditing event* `os.exec` with arguments `path`, `args`, `env`.

Availability: Unix, Windows, not WASI, not Android, not iOS.

Changed in version 3.3: Added support for specifying *path* as an open file descriptor for *execve()*.

Changed in version 3.6: Accepts a *path-like object*.

`os._exit(n)`

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

> **Note**
>
> The standard way to exit is *sys.exit(n)*. `_exit()` should normally only be used in the child process after a *fork()*.

The following exit codes are defined and can be used with *_exit()*, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

> **Note**
>
> Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

os.EX_OK

Exit code that means no error occurred. May be taken from the defined value of `EXIT_SUCCESS` on some platforms. Generally has a value of zero.

Availability: Unix, Windows.

os.EX_USAGE

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

Availability: Unix, not WASI.

os.**EX_DATAERR**

Exit code that means the input data was incorrect.

Availability: Unix, not WASI.

os.**EX_NOINPUT**

Exit code that means an input file did not exist or was not readable.

Availability: Unix, not WASI.

os.**EX_NOUSER**

Exit code that means a specified user did not exist.

Availability: Unix, not WASI.

os.**EX_NOHOST**

Exit code that means a specified host did not exist.

Availability: Unix, not WASI.

os.**EX_UNAVAILABLE**

Exit code that means that a required service is unavailable.

Availability: Unix, not WASI.

os.**EX_SOFTWARE**

Exit code that means an internal software error was detected.

Availability: Unix, not WASI.

os.**EX_OSERR**

Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

Availability: Unix, not WASI.

os.**EX_OSFILE**

Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

Availability: Unix, not WASI.

os.**EX_CANTCREAT**

Exit code that means a user specified output file could not be created.

Availability: Unix, not WASI.

os.**EX_IOERR**

Exit code that means that an error occurred while doing I/O on some file.

Availability: Unix, not WASI.

os.**EX_TEMPFAIL**

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

Availability: Unix, not WASI.

os.**EX_PROTOCOL**

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

Availability: Unix, not WASI.

os.**EX_NOPERM**

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

Availability: Unix, not WASI.

os.**EX_CONFIG**

Exit code that means that some kind of configuration error occurred.

Availability: Unix, not WASI.

os.**EX_NOTFOUND**

Exit code that means something like "an entry was not found".

Availability: Unix, not WASI.

os.**fork**()

Fork a child process. Return `0` in the child and the child's process id in the parent. If an error occurs *OSError* is raised.

Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using `fork()` from a thread.

Raises an *auditing event* `os.fork` with no arguments.

Warning

If you use TLS sockets in an application calling `fork()`, see the warning in the *ssl* documentation.

Warning

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using *urllib.request*.

Changed in version 3.8: Calling `fork()` in a subinterpreter is no longer supported (*RuntimeError* is raised).

Changed in version 3.12: If Python is able to detect that your process has multiple threads, *os.fork()* now raises a *DeprecationWarning*.

We chose to surface this as a warning, when detectable, to better inform developers of a design problem that the POSIX platform specifically notes as not supported. Even in code that *appears* to work, it has never been safe to mix threading with *os.fork()* on POSIX platforms. The CPython runtime itself has always made API calls that are not safe for use in the child process when threads existed in the parent (such as `malloc` and `free`).

Users of macOS or users of libc or malloc implementations other than those typically found in glibc to date are among those already more likely to experience deadlocks running such code.

See this discussion on fork being incompatible with threads for technical details of why we're surfacing this longstanding platform compatibility problem to developers.

Availability: POSIX, not WASI, not Android, not iOS.

os.**forkpty**()

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of `(pid, fd)`, where *pid* is `0` in the child, the new child's process id in the parent, and *fd* is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the *pty* module. If an error occurs *OSError* is raised.

Raises an *auditing event* `os.forkpty` with no arguments.

Warning

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using *urllib.request*.

Changed in version 3.8: Calling `forkpty()` in a subinterpreter is no longer supported (*RuntimeError* is raised).

Changed in version 3.12: If Python is able to detect that your process has multiple threads, this now raises a *DeprecationWarning*. See the longer explanation on *os.fork()*.

Availability: Unix, not WASI, not Android, not iOS.

`os.`**`kill`**(*pid*, *sig*, */*)

Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the *signal* module.

Windows: The *signal.CTRL_C_EVENT* and *signal.CTRL_BREAK_EVENT* signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the TerminateProcess API, and the exit code will be set to *sig*.

See also *signal.pthread_kill()*.

Raises an *auditing event* `os.kill` with arguments `pid`, `sig`.

Availability: Unix, Windows, not WASI, not iOS.

Changed in version 3.2: Added Windows support.

`os.`**`killpg`**(*pgid*, *sig*, */*)

Send the signal *sig* to the process group *pgid*.

Raises an *auditing event* `os.killpg` with arguments `pgid`, `sig`.

Availability: Unix, not WASI, not iOS.

`os.`**`nice`**(*increment*, */*)

Add *increment* to the process's "niceness". Return the new niceness.

Availability: Unix, not WASI.

`os.`**`pidfd_open`**(*pid*, *flags=0*)

Return a file descriptor referring to the process *pid* with *flags* set. This descriptor can be used to perform process management without races and signals.

See the *pidfd_open(2)* man page for more details.

Availability: Linux >= 5.3, Android >= *build-time* API level 31

Added in version 3.9.

`os.`**`PIDFD_NONBLOCK`**

This flag indicates that the file descriptor will be non-blocking. If the process referred to by the file descriptor has not yet terminated, then an attempt to wait on the file descriptor using *waitid(2)* will immediately return the error *EAGAIN* rather than blocking.

Availability: Linux >= 5.10

Added in version 3.12.

`os.`**`plock`**(*op*, */*)

Lock program segments into memory. The value of *op* (defined in `<sys/lock.h>`) determines which segments are locked.

Availability: Unix, not WASI, not iOS.

`os.`**`popen`**(*cmd*, *mode='r'*, *buffering=-1*)

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is `'r'` (default) or `'w'`. The *buffering* argument have the same meaning as the corresponding argument to the built-in *open()* function. The returned file object reads or writes text strings rather than bytes.

The `close` method returns *None* if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be `- signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

On Unix, *waitstatus_to_exitcode()* can be used to convert the `close` method result (exit status) into an exit code if it is not `None`. On Windows, the `close` method result is directly the exit code (or `None`).

This is implemented using *subprocess.Popen*; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

Availability: not WASI, not Android, not iOS.

Note

The *Python UTF-8 Mode* affects encodings used for *cmd* and pipe contents.

popen() is a simple wrapper around *subprocess.Popen*. Use *subprocess.Popen* or *subprocess.run()* to control options like encodings.

`os.`**`posix_spawn`**(*path*, *argv*, *env*, *, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the `posix_spawn()` C library API for use from Python.

Most users should use *subprocess.run()* instead of *posix_spawn()*.

The positional-only arguments *path*, *args*, and *env* are similar to *execve()*. *env* is allowed to be `None`, in which case current process' environment is used.

The *path* parameter is the path to the executable file. The *path* should contain a directory. Use *posix_spawnp()* to pass an executable file without directory.

The *file_actions* argument may be a sequence of tuples describing actions to take on specific file descriptors in the child process between the C library implementation's `fork()` and `exec()` steps. The first item in each tuple must be one of the three type indicator listed below describing the remaining tuple elements:

`os.`**`POSIX_SPAWN_OPEN`**

(`os.POSIX_SPAWN_OPEN`, *fd*, *path*, *flags*, *mode*)

Performs `os.dup2(os.open(path, flags, mode), fd)`.

`os.`**`POSIX_SPAWN_CLOSE`**

(`os.POSIX_SPAWN_CLOSE`, *fd*)

Performs `os.close(fd)`.

`os.`**`POSIX_SPAWN_DUP2`**

(`os.POSIX_SPAWN_DUP2`, *fd*, *new_fd*)

Performs `os.dup2(fd, new_fd)`.

`os.`**`POSIX_SPAWN_CLOSEFROM`**

(`os.POSIX_SPAWN_CLOSEFROM`, *fd*)

Performs `os.closerange(fd, INF)`.

These tuples correspond to the C library `posix_spawn_file_actions_addopen()`, `posix_spawn_file_actions_addclose()`, `posix_spawn_file_actions_adddup2()`, and `posix_spawn_file_actions_addclosefrom_np()` API calls used to prepare for the `posix_spawn()` call itself.

The *setpgroup* argument will set the process group of the child to the value specified. If the value specified is 0, the child's process group ID will be made the same as its process ID. If the value of *setpgroup*

is not set, the child will inherit the parent's process group ID. This argument corresponds to the C library `POSIX_SPAWN_SETPGROUP` flag.

If the *resetids* argument is `True` it will reset the effective UID and GID of the child to the real UID and GID of the parent process. If the argument is `False`, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file, their effect will override the setting of the effective UID and GID. This argument corresponds to the C library `POSIX_SPAWN_RESETIDS` flag.

If the *setsid* argument is `True`, it will create a new session ID for `posix_spawn`. *setsid* requires `POSIX_SPAWN_SETSID` or `POSIX_SPAWN_SETSID_NP` flag. Otherwise, *NotImplementedError* is raised.

The *setsigmask* argument will set the signal mask to the signal set specified. If the parameter is not used, then the child inherits the parent's signal mask. This argument corresponds to the C library `POSIX_SPAWN_SETSIGMASK` flag.

The *sigdef* argument will reset the disposition of all signals in the set specified. This argument corresponds to the C library `POSIX_SPAWN_SETSIGDEF` flag.

The *scheduler* argument must be a tuple containing the (optional) scheduler policy and an instance of *sched_param* with the scheduler parameters. A value of `None` in the place of the scheduler policy indicates that is not being provided. This argument is a combination of the C library `POSIX_SPAWN_SETSCHEDPARAM` and `POSIX_SPAWN_SETSCHEDULER` flags.

Raises an *auditing event* `os.posix_spawn` with arguments `path`, `argv`, `env`.

Added in version 3.8.

Changed in version 3.13: *env* parameter accepts `None`. `os.POSIX_SPAWN_CLOSEFROM` is available on platforms where `posix_spawn_file_actions_addclosefrom_np()` exists.

Availability: Unix, not WASI, not Android, not iOS.

`os.`**`posix_spawnp`**(*path*, *argv*, *env*, ***, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the `posix_spawnp()` C library API for use from Python.

Similar to *posix_spawn()* except that the system searches for the *executable* file in the list of directories specified by the `PATH` environment variable (in the same way as for `execvp(3)`).

Raises an *auditing event* `os.posix_spawn` with arguments `path`, `argv`, `env`.

Added in version 3.8.

Availability: POSIX, not WASI, not Android, not iOS.

See *posix_spawn()* documentation.

`os.`**`register_at_fork`**(***, *before=None*, *after_in_parent=None*, *after_in_child=None*)

Register callables to be executed when a new child process is forked using *os.fork()* or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after_in_parent* is a function called from the parent process after forking a child process.
- *after_in_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical *subprocess* launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that `fork()` calls made by third-party C code may not call those functions, unless it explicitly calls `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

There is no way to unregister a function.

Availability: Unix, not WASI, not Android, not iOS.

Added in version 3.7.

os.**spawnl**(*mode*, *path*, *...*)

os.**spawnle**(*mode*, *path*, *...*, *env*)

os.**spawnlp**(*mode*, *file*, *...*)

os.**spawnlpe**(*mode*, *file*, *...*, *env*)

os.**spawnv**(*mode*, *path*, *args*)

os.**spawnve**(*mode*, *path*, *args*, *env*)

os.**spawnvp**(*mode*, *file*, *args*)

os.**spawnvpe**(*mode*, *file*, *args*, *env*)

Execute the program *path* in a new process.

(Note that the *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the *Replacing Older Functions with the subprocess Module* section.)

If *mode* is *P_NOWAIT*, this function returns the process id of the new process; if *mode* is *P_WAIT*, returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the *waitpid()* function.

Note on VxWorks, this function doesn't return `-signal` when the new process is killed. Instead it raises OSError exception.

The "l" and "v" variants of the *spawn** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `spawnl*()` functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second "p" near the end (*spawnlp()*, *spawnlpe()*, *spawnvp()*, and *spawnvpe()*) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the *spawn*e* variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, *spawnl()*, *spawnle()*, *spawnv()*, and *spawnve()*, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For *spawnle()*, *spawnlpe()*, *spawnve()*, and *spawnvpe()* (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions *spawnl()*, *spawnlp()*, *spawnv()*, and *spawnvp()* all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of `127`.

As an example, the following calls to *spawnlp()* and *spawnvpe()* are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Raises an *auditing event* `os.spawn` with arguments `mode`, `path`, `args`, `env`.

Availability: Unix, Windows, not WASI, not Android, not iOS.

spawnlp(), *spawnlpe()*, *spawnvp()* and *spawnvpe()* are not available on Windows. *spawnle()* and *spawnve()* are not thread-safe on Windows; we advise you to use the *subprocess* module instead.

Changed in version 3.6: Accepts a *path-like object*.

os.**P_NOWAIT**

os.**P_NOWAITO**

Possible values for the *mode* parameter to the *spawn** family of functions. If either of these values is given, the *spawn** functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

os.**P_WAIT**

Possible value for the *mode* parameter to the *spawn** family of functions. If this is given as *mode*, the *spawn** functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

Availability: Unix, Windows.

os.**P_DETACH**

os.**P_OVERLAY**

Possible values for the *mode* parameter to the *spawn** family of functions. These are less portable than those listed above. *P_DETACH* is similar to *P_NOWAIT*, but the new process is detached from the console of the calling process. If *P_OVERLAY* is used, the current process will be replaced; the *spawn** function will not return.

Availability: Windows.

os.**startfile**(*path*[, *operation*][, *arguments*][, *cwd*][, *show_cmd*])

Start a file with its associated application.

When *operation* is not specified, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the **start** command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a "command verb" that specifies what should be done with the file. Common verbs documented by Microsoft are `'open'`, `'print'` and `'edit'` (to be used on files) as well as `'explore'` and `'find'` (to be used on directories).

When launching an application, specify *arguments* to be passed as a single string. This argument may have no effect when using this function to launch a document.

The default working directory is inherited, but may be overridden by the *cwd* argument. This should be an absolute path. A relative *path* will be resolved against this argument.

Use *show_cmd* to override the default window style. Whether this has any effect will depend on the application being launched. Values are integers as supported by the Win32 `ShellExecute()` function.

startfile() returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The *path* parameter is relative to the current directory or *cwd*. If you want to use an absolute path, make sure the first character is not a slash (`'/'`) Use *pathlib* or the *os.path.normpath()* function to ensure that paths are properly encoded for Win32.

To reduce interpreter startup overhead, the Win32 `ShellExecute()` function is not resolved until this function is first called. If the function cannot be resolved, *NotImplementedError* will be raised.

Raises an *auditing event* `os.startfile` with arguments `path`, `operation`.

Raises an *auditing event* `os.startfile/2` with arguments `path`, `operation`, `arguments`, `cwd`, `show_cmd`.

Availability: Windows.

Changed in version 3.10: Added the *arguments*, *cwd* and *show_cmd* arguments, and the `os.startfile/2` audit event.

os.**system**(*command*)

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to *sys.stdin*, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output

stream. The C standard does not specify the meaning of the return value of the C function, so the return value of the Python function is system-dependent.

On Unix, the return value is the exit status of the process encoded in the format specified for *wait()*.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable COMSPEC: it is usually **cmd.exe**, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the *Replacing Older Functions with the subprocess Module* section in the *subprocess* documentation for some helpful recipes.

On Unix, *waitstatus_to_exitcode()* can be used to convert the result (exit status) into an exit code. On Windows, the result is directly the exit code.

Raises an *auditing event* `os.system` with argument `command`.

Availability: Unix, Windows, not WASI, not Android, not iOS.

`os.`**`times`**`()`

Returns the current global process times. The return value is an object with five attributes:

- `user` - user time
- `system` - system time
- `children_user` - user time of all child processes
- `children_system` - system time of all child processes
- `elapsed` - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing `user`, `system`, `children_user`, `children_system`, and `elapsed` in that order.

See the Unix manual page *times(2)* and times(3) manual page on Unix or the GetProcessTimes MSDN on Windows. On Windows, only `user` and `system` are known; the other attributes are zero.

Availability: Unix, Windows.

Changed in version 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

`os.`**`wait`**`()`

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

If there are no children that could be waited for, *ChildProcessError* is raised.

waitstatus_to_exitcode() can be used to convert the exit status into an exit code.

Availability: Unix, not WASI, not Android, not iOS.

See also

The other `wait*()` functions documented below can be used to wait for the completion of a specific child process and have more options. *waitpid()* is the only one also available on Windows.

`os.`**`waitid`**`(`*idtype*, *id*, *options*, **/**`)`

Wait for the completion of a child process.

idtype can be *P_PID*, *P_PGID*, *P_ALL*, or (on Linux) *P_PIDFD*. The interpretation of *id* depends on it; see their individual descriptions.

options is an OR combination of flags. At least one of *WEXITED*, *WSTOPPED* or *WCONTINUED* is required; *WNOHANG* and *WNOWAIT* are additional optional flags.

The return value is an object representing the data contained in the `siginfo_t` structure with the following attributes:

- `si_pid` (process ID)
- `si_uid` (real user ID of the child)
- `si_signo` (always *SIGCHLD*)
- `si_status` (the exit status or signal number, depending on `si_code`)
- `si_code` (see *CLD_EXITED* for possible values)

If *WNOHANG* is specified and there are no matching children in the requested state, `None` is returned. Otherwise, if there are no matching children that could be waited for, *ChildProcessError* is raised.

Availability: Unix, not WASI, not Android, not iOS.

Added in version 3.3.

Changed in version 3.13: This function is now available on macOS as well.

`os.`**`waitpid`**(*pid*, *options*, `/`)

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for *wait()*). The semantics of the call are affected by the value of the integer *options*, which should be `0` for normal operation.

If *pid* is greater than `0`, *waitpid()* requests status information for that specific process. If *pid* is `0`, the request is for the status of any child in the process group of the current process. If *pid* is `-1`, the request pertains to any child of the current process. If *pid* is less than `-1`, status is requested for any process in the process group `-pid` (the absolute value of *pid*).

options is an OR combination of flags. If it contains *WNOHANG* and there are no matching children in the requested state, `(0, 0)` is returned. Otherwise, if there are no matching children that could be waited for, *ChildProcessError* is raised. Other options that can be used are *WUNTRACED* and *WCONTINUED*.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to `0` has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The *spawn** functions called with *P_NOWAIT* return suitable process handles.

waitstatus_to_exitcode() can be used to convert the exit status into an exit code.

Availability: Unix, Windows, not WASI, not Android, not iOS.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

`os.`**`wait3`**(*options*)

Similar to *waitpid()*, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The *options* argument is the same as that provided to *waitpid()* and *wait4()*.

waitstatus_to_exitcode() can be used to convert the exit status into an exitcode.

Availability: Unix, not WASI, not Android, not iOS.

`os.`**`wait4`**(*pid*, *options*)

Similar to *waitpid()*, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The arguments to *wait4()* are the same as those provided to *waitpid()*.

waitstatus_to_exitcode() can be used to convert the exit status into an exitcode.

Availability: Unix, not WASI, not Android, not iOS.

os.**P_PID**

os.**P_PGID**

os.**P_ALL**

os.**P_PIDFD**

These are the possible values for *idtype* in `waitid()`. They affect how *id* is interpreted:

- `P_PID` - wait for the child whose PID is *id*.
- `P_PGID` - wait for any child whose progress group ID is *id*.
- `P_ALL` - wait for any child; *id* is ignored.
- `P_PIDFD` - wait for the child identified by the file descriptor *id* (a process file descriptor created with `pidfd_open()`).

Availability: Unix, not WASI, not Android, not iOS.

> **Note**
>
> `P_PIDFD` is only available on Linux >= 5.4.

Added in version 3.3.

Added in version 3.9: The `P_PIDFD` constant.

os.**WCONTINUED**

This *options* flag for `waitpid()`, `wait3()`, `wait4()`, and `waitid()` causes child processes to be reported if they have been continued from a job control stop since they were last reported.

Availability: Unix, not WASI, not Android, not iOS.

os.**WEXITED**

This *options* flag for `waitid()` causes child processes that have terminated to be reported.

The other `wait*` functions always report children that have terminated, so this option is not available for them.

Availability: Unix, not WASI, not Android, not iOS.

Added in version 3.3.

os.**WSTOPPED**

This *options* flag for `waitid()` causes child processes that have been stopped by the delivery of a signal to be reported.

This option is not available for the other `wait*` functions.

Availability: Unix, not WASI, not Android, not iOS.

Added in version 3.3.

os.**WUNTRACED**

This *options* flag for `waitpid()`, `wait3()`, and `wait4()` causes child processes to also be reported if they have been stopped but their current state has not been reported since they were stopped.

This option is not available for `waitid()`.

Availability: Unix, not WASI, not Android, not iOS.

os.**WNOHANG**

This *options* flag causes `waitpid()`, `wait3()`, `wait4()`, and `waitid()` to return right away if no child process status is available immediately.

Availability: Unix, not WASI, not Android, not iOS.

os.**WNOWAIT**

This *options* flag causes *waitid()* to leave the child in a waitable state, so that a later `wait*()` call can be used to retrieve the child status information again.

This option is not available for the other `wait*` functions.

Availability: Unix, not WASI, not Android, not iOS.

os.**CLD_EXITED**

os.**CLD_KILLED**

os.**CLD_DUMPED**

os.**CLD_TRAPPED**

os.**CLD_STOPPED**

os.**CLD_CONTINUED**

These are the possible values for `si_code` in the result returned by *waitid()*.

Availability: Unix, not WASI, not Android, not iOS.

Added in version 3.3.

Changed in version 3.9: Added *CLD_KILLED* and *CLD_STOPPED* values.

os.**waitstatus_to_exitcode**(*status*)

Convert a wait status to an exit code.

On Unix:

- If the process exited normally (if `WIFEXITED(status)` is true), return the process exit status (return `WEXITSTATUS(status)`): result greater than or equal to 0.
- If the process was terminated by a signal (if `WIFSIGNALED(status)` is true), return `-signum` where *signum* is the number of the signal that caused the process to terminate (return `-WTERMSIG(status)`): result less than 0.
- Otherwise, raise a *ValueError*.

On Windows, return *status* shifted right by 8 bits.

On Unix, if the process is being traced or if *waitpid()* was called with *WUNTRACED* option, the caller must first check if `WIFSTOPPED(status)` is true. This function must not be called if `WIFSTOPPED(status)` is true.

See also

WIFEXITED(), *WEXITSTATUS()*, *WIFSIGNALED()*, *WTERMSIG()*, *WIFSTOPPED()*, *WSTOPSIG()* functions.

Availability: Unix, Windows, not WASI, not Android, not iOS.

Added in version 3.9.

The following functions take a process status code as returned by *system()*, *wait()*, or *waitpid()* as a parameter. They may be used to determine the disposition of a process.

os.**WCOREDUMP**(*status*, /)

Return `True` if a core dump was generated for the process, otherwise return `False`.

This function should be employed only if *WIFSIGNALED()* is true.

Availability: Unix, not WASI, not Android, not iOS.

os.**WIFCONTINUED**(*status*)

Return `True` if a stopped child has been resumed by delivery of *SIGCONT* (if the process has been continued from a job control stop), otherwise return `False`.

See *WCONTINUED* option.

Availability: Unix, not WASI, not Android, not iOS.

os.**WIFSTOPPED**(*status*)

Return `True` if the process was stopped by delivery of a signal, otherwise return `False`.

WIFSTOPPED() only returns `True` if the *waitpid()* call was done using *WUNTRACED* option or when the process is being traced (see *ptrace(2)*).

Availability: Unix, not WASI, not Android, not iOS.

os.**WIFSIGNALED**(*status*)

Return `True` if the process was terminated by a signal, otherwise return `False`.

Availability: Unix, not WASI, not Android, not iOS.

os.**WIFEXITED**(*status*)

Return `True` if the process exited terminated normally, that is, by calling `exit()` or `_exit()`, or by returning from `main()`; otherwise return `False`.

Availability: Unix, not WASI, not Android, not iOS.

os.**WEXITSTATUS**(*status*)

Return the process exit status.

This function should be employed only if *WIFEXITED()* is true.

Availability: Unix, not WASI, not Android, not iOS.

os.**WSTOPSIG**(*status*)

Return the signal which caused the process to stop.

This function should be employed only if *WIFSTOPPED()* is true.

Availability: Unix, not WASI, not Android, not iOS.

os.**WTERMSIG**(*status*)

Return the number of the signal that caused the process to terminate.

This function should be employed only if *WIFSIGNALED()* is true.

Availability: Unix, not WASI, not Android, not iOS.

16.1.8 Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

Added in version 3.3.

The following scheduling policies are exposed if they are supported by the operating system.

os.**SCHED_OTHER**

The default scheduling policy.

os.**SCHED_BATCH**

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

os.**SCHED_IDLE**

Scheduling policy for extremely low priority background tasks.

os.**SCHED_SPORADIC**

Scheduling policy for sporadic server programs.

os.**SCHED_FIFO**

A First In First Out scheduling policy.

os.**SCHED_RR**

A round-robin scheduling policy.

os.**SCHED_RESET_ON_FORK**

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

class os.**sched_param**(*sched_priority*)

This class represents tunable scheduling parameters used in *sched_setparam()*, *sched_setscheduler()*, and *sched_getparam()*. It is immutable.

At the moment, there is only one possible parameter:

sched_priority

The scheduling priority for a scheduling policy.

os.**sched_get_priority_min**(*policy*)

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.**sched_get_priority_max**(*policy*)

Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.**sched_setscheduler**(*pid*, *policy*, *param*, /)

Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a *sched_param* instance.

os.**sched_getscheduler**(*pid*, /)

Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

os.**sched_setparam**(*pid*, *param*, /)

Set the scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a *sched_param* instance.

os.**sched_getparam**(*pid*, /)

Return the scheduling parameters as a *sched_param* instance for the process with PID *pid*. A *pid* of 0 means the calling process.

os.**sched_rr_get_interval**(*pid*, /)

Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

os.**sched_yield**()

Voluntarily relinquish the CPU. See *sched_yield(2)* for details.

os.**sched_setaffinity**(*pid*, *mask*, /)

Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

os.**sched_getaffinity**(*pid*, /)

Return the set of CPUs the process with PID *pid* is restricted to.

If *pid* is zero, return the set of CPUs the calling thread of the current process is restricted to.

See also the *process_cpu_count()* function.

16.1.9 Miscellaneous System Information

os.**confstr**(*name*, /)

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

Availability: Unix.

os.**confstr_names**

Dictionary mapping names accepted by *confstr()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

os.**cpu_count**()

Return the number of logical CPUs in the **system**. Returns `None` if undetermined.

The *process_cpu_count()* function can be used to get the number of logical CPUs usable by the calling thread of the **current process**.

Added in version 3.4.

Changed in version 3.13: If `-X cpu_count` is given or `PYTHON_CPU_COUNT` is set, *cpu_count()* returns the overridden value *n*.

os.**getloadavg**()

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises *OSError* if the load average was unobtainable.

Availability: Unix.

os.**process_cpu_count**()

Get the number of logical CPUs usable by the calling thread of the **current process**. Returns `None` if undetermined. It can be less than *cpu_count()* depending on the CPU affinity.

The *cpu_count()* function can be used to get the number of logical CPUs in the **system**.

If `-X cpu_count` is given or `PYTHON_CPU_COUNT` is set, *process_cpu_count()* returns the overridden value *n*.

See also the *sched_getaffinity()* function.

Added in version 3.13.

os.**sysconf**(*name*, /)

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for *confstr()* apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

Availability: Unix.

os.**sysconf_names**

Dictionary mapping names accepted by *sysconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

Changed in version 3.11: Add `'SC_MINSIGSTKSZ'` name.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the *os.path* module.

os.**curdir**

The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via *os.path*.

os.**pardir**

The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via *os.path*.

os.**sep**

The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use *os.path.split()* and *os.path.join()* — but it is occasionally useful. Also available via *os.path*.

os.**altsep**

An alternative character used by the operating system to separate pathname components, or `None` if only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via *os.path*.

os.**extsep**

The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via *os.path*.

os.**pathsep**

The character conventionally used by the operating system to separate search path components (as in `PATH`), such as `':'` for POSIX or `';'` for Windows. Also available via *os.path*.

os.**defpath**

The default search path used by *exec*p** and *spawn*p** if the environment doesn't have a `'PATH'` key. Also available via *os.path*.

os.**linesep**

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use *os.linesep* as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

os.**devnull**

The file path of the null device. For example: `'/dev/null'` for POSIX, `'nul'` for Windows. Also available via *os.path*.

os.**RTLD_LAZY**

os.**RTLD_NOW**

os.**RTLD_GLOBAL**

os.**RTLD_LOCAL**

os.**RTLD_NODELETE**

os.**RTLD_NOLOAD**

os.**RTLD_DEEPBIND**

Flags for use with the *setdlopenflags()* and *getdlopenflags()* functions. See the Unix manual page *dlopen(3)* for what the different flags mean.

Added in version 3.3.

16.1.10 Random numbers

os.**getrandom**(*size*, *flags=0*)

Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The flags argument is a bit mask that can contain zero or more of the following values ORed together: *os.GRND_RANDOM* and *GRND_NONBLOCK*.

See also the Linux getrandom() manual page.

Availability: Linux >= 3.17.

Added in version 3.6.

os.**urandom**(*size*, */*)

Return a bytestring of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the **PEP 524** for the rationale. On Linux, the *getrandom()* function can be used to get random bytes in non-blocking mode (using the *GRND_NONBLOCK* flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the *NotImplementedError* exception is raised.

On Windows, it will use `BCryptGenRandom()`.

See also

The *secrets* module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see *random.SystemRandom*.

Changed in version 3.5: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

Changed in version 3.5.2: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

Changed in version 3.6: On Linux, `getrandom()` is now used in blocking mode to increase the security.

Changed in version 3.11: On Windows, `BCryptGenRandom()` is used instead of `CryptGenRandom()` which is deprecated.

os.**GRND_NONBLOCK**

By default, when reading from `/dev/random`, *getrandom()* blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the *GRND_NONBLOCK* flag is set, then *getrandom()* does not block in these cases, but instead immediately raises *BlockingIOError*.

Added in version 3.6.

os.**GRND_RANDOM**

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

Added in version 3.6.

16.2 io — Core tools for working with streams

Source code: Lib/io.py

16.2.1 Overview

The *io* module provides Python's main facilities for dealing with various types of I/O. There are three main types of I/O: *text I/O*, *binary I/O* and *raw I/O*. These are generic categories, and various backing stores can be used for each of them. A concrete object belonging to any of these categories is called a *file object*. Other common terms are *stream* and *file-like object*.

Independent of its category, each concrete stream object will also have various capabilities: it can be read-only, write-only, or read-write. It can also allow arbitrary random access (seeking forwards or backwards to any location), or only sequential access (for example in the case of a socket or pipe).

All streams are careful about the type of data you give to them. For example giving a *str* object to the `write()` method of a binary stream will raise a *TypeError*. So will giving a *bytes* object to the `write()` method of a text stream.

Changed in version 3.3: Operations that used to raise *IOError* now raise *OSError*, since *IOError* is now an alias of *OSError*.

Text I/O

Text I/O expects and produces *str* objects. This means that whenever the backing store is natively made of bytes (such as in the case of a file), encoding and decoding of data is made transparently as well as optional translation of platform-specific newline characters.

The easiest way to create a text stream is with *open()*, optionally specifying an encoding:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

In-memory text streams are also available as *StringIO* objects:

```
f = io.StringIO("some initial text data")
```

The text stream API is described in detail in the documentation of *TextIOBase*.

Binary I/O

Binary I/O (also called *buffered I/O*) expects *bytes-like objects* and produces *bytes* objects. No encoding, decoding, or newline translation is performed. This category of streams can be used for all kinds of non-text data, and also when manual control over the handling of text data is desired.

The easiest way to create a binary stream is with *open()* with `'b'` in the mode string:

```
f = open("myfile.jpg", "rb")
```

In-memory binary streams are also available as *BytesIO* objects:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

The binary stream API is described in detail in the docs of *BufferedIOBase*.

Other library modules may provide additional ways to create text or binary streams. See *socket.socket.makefile()* for example.

Raw I/O

Raw I/O (also called *unbuffered I/O*) is generally used as a low-level building-block for binary and text streams; it is rarely useful to directly manipulate a raw stream from user code. Nevertheless, you can create a raw stream by opening a file in binary mode with buffering disabled:

```
f = open("myfile.jpg", "rb", buffering=0)
```

The raw stream API is described in detail in the docs of *RawIOBase*.

16.2.2 Text Encoding

The default encoding of *TextIOWrapper* and *open()* is locale-specific (*locale.getencoding()*).

However, many developers forget to specify the encoding when opening text files encoded in UTF-8 (e.g. JSON, TOML, Markdown, etc…) since most Unix platforms use UTF-8 locale by default. This causes bugs because the locale encoding is not UTF-8 for most Windows users. For example:

```
# May not work on Windows when non-ASCII characters in the file.
with open("README.md") as f:
    long_description = f.read()
```

Accordingly, it is highly recommended that you specify the encoding explicitly when opening text files. If you want to use UTF-8, pass `encoding="utf-8"`. To use the current locale encoding, `encoding="locale"` is supported since Python 3.10.

See also

Python UTF-8 Mode
: Python UTF-8 Mode can be used to change the default encoding to UTF-8 from locale-specific encoding.

PEP 686
: Python 3.15 will make *Python UTF-8 Mode* default.

Opt-in EncodingWarning

Added in version 3.10: See **PEP 597** for more details.

To find where the default locale encoding is used, you can enable the `-X warn_default_encoding` command line option or set the `PYTHONWARNDEFAULTENCODING` environment variable, which will emit an *EncodingWarning* when the default encoding is used.

If you are providing an API that uses *open()* or *TextIOWrapper* and passes `encoding=None` as a parameter, you can use *text_encoding()* so that callers of the API will emit an *EncodingWarning* if they don't pass an `encoding`. However, please consider using UTF-8 by default (i.e. `encoding="utf-8"`) for new APIs.

16.2.3 High-level Module Interface

`io.`**DEFAULT_BUFFER_SIZE**

An int containing the default buffer size used by the module's buffered I/O classes. *open()* uses the file's blksize (as obtained by *os.stat()*) if possible.

`io.`**open**(*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)

This is an alias for the builtin *open()* function.

This function raises an *auditing event* `open` with arguments *path*, *mode* and *flags*. The *mode* and *flags* arguments may have been modified or inferred from the original call.

io.**open_code**(*path*)

Opens the provided file with mode `'rb'`. This function should be used when the intent is to treat the contents as executable code.

path should be a *str* and an absolute path.

The behavior of this function may be overridden by an earlier call to the `PyFile_SetOpenCodeHook()`. However, assuming that *path* is a *str* and an absolute path, `open_code(path)` should always behave the same as `open(path, 'rb')`. Overriding the behavior is intended for additional validation or preprocessing of the file.

Added in version 3.8.

io.**text_encoding**(*encoding*, *stacklevel=2*, */*)

This is a helper function for callables that use *open()* or *TextIOWrapper* and have an `encoding=None` parameter.

This function returns *encoding* if it is not `None`. Otherwise, it returns `"locale"` or `"utf-8"` depending on *UTF-8 Mode*.

This function emits an *EncodingWarning* if *sys.flags.warn_default_encoding* is true and *encoding* is `None`. *stacklevel* specifies where the warning is emitted. For example:

```
def read_text(path, encoding=None):
    encoding = io.text_encoding(encoding)  # stacklevel=2
    with open(path, encoding) as f:
        return f.read()
```

In this example, an *EncodingWarning* is emitted for the caller of `read_text()`.

See *Text Encoding* for more information.

Added in version 3.10.

Changed in version 3.11: *text_encoding()* returns "utf-8" when UTF-8 mode is enabled and *encoding* is `None`.

exception io.**BlockingIOError**

This is a compatibility alias for the builtin *BlockingIOError* exception.

exception io.**UnsupportedOperation**

An exception inheriting *OSError* and *ValueError* that is raised when an unsupported operation is called on a stream.

See also

sys
contains the standard IO streams: *sys.stdin*, *sys.stdout*, and *sys.stderr*.

16.2.4 Class hierarchy

The implementation of I/O streams is organized as a hierarchy of classes. First *abstract base classes* (ABCs), which are used to specify the various categories of streams, then concrete classes providing the standard stream implementations.

Note

The abstract base classes also provide default implementations of some methods in order to help implementation of concrete stream classes. For example, *BufferedIOBase* provides unoptimized implementations of `readinto()` and `readline()`.

At the top of the I/O hierarchy is the abstract base class *IOBase*. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise *UnsupportedOperation* if they do not support a given operation.

The *RawIOBase* ABC extends *IOBase*. It deals with the reading and writing of bytes to a stream. *FileIO* subclasses *RawIOBase* to provide an interface to files in the machine's file system.

The *BufferedIOBase* ABC extends *IOBase*. It deals with buffering on a raw binary stream (*RawIOBase*). Its subclasses, *BufferedWriter*, *BufferedReader*, and *BufferedRWPair* buffer raw binary streams that are writable, readable, and both readable and writable, respectively. *BufferedRandom* provides a buffered interface to seekable streams. Another *BufferedIOBase* subclass, *BytesIO*, is a stream of in-memory bytes.

The *TextIOBase* ABC extends *IOBase*. It deals with streams whose bytes represent text, and handles encoding and decoding to and from strings. *TextIOWrapper*, which extends *TextIOBase*, is a buffered text interface to a buffered raw stream (*BufferedIOBase*). Finally, *StringIO* is an in-memory stream for text.

Argument names are not part of the specification, and only the arguments of *open()* are intended to be used as keyword arguments.

The following table summarizes the ABCs provided by the *io* module:

ABC	Inherits	Stub Methods	Mixin Methods and Properties
IOBase		`fileno`, `seek`, and `truncate`	`close`, `closed`, `__enter__`, `__exit__`, `flush`, `isatty`, `__iter__`, `__next__`, `readable`, `readline`, `readlines`, `seekable`, `tell`, `writable`, and `writelines`
RawIOBase	*IOBase*	`readinto` and `write`	Inherited *IOBase* methods, `read`, and `readall`
BufferedIOBase	*IOBase*	`detach`, `read`, `read1`, and `write`	Inherited *IOBase* methods, `readinto`, and `readinto1`
TextIOBase	*IOBase*	`detach`, `read`, `readline`, and `write`	Inherited *IOBase* methods, `encoding`, `errors`, and `newlines`

I/O Base Classes

class io.**IOBase**

The abstract base class for all I/O classes.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or seeked.

Even though *IOBase* does not declare `read()` or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a *ValueError* (or *UnsupportedOperation*) when operations they do not support are called.

The basic type used for binary data read from or written to a file is *bytes*. Other *bytes-like objects* are accepted as method arguments too. Text I/O classes work with *str* data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise *ValueError* in this case.

IOBase (and its subclasses) supports the iterator protocol, meaning that an *IOBase* object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See *readline()* below.

IOBase is also a context manager and therefore supports the `with` statement. In this example, *file* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

IOBase provides these data attributes and methods:

close()

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a *ValueError*.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

closed

`True` if the stream is closed.

fileno()

Return the underlying file descriptor (an integer) of the stream if it exists. An *OSError* is raised if the IO object does not use a file descriptor.

flush()

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

isatty()

Return `True` if the stream is interactive (i.e., connected to a terminal/tty device).

readable()

Return `True` if the stream can be read from. If `False`, `read()` will raise *OSError*.

readline(*size=-1*, */*)

Read and return one line from the stream. If *size* is specified, at most *size* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newline* argument to *open()* can be used to select the line terminator(s) recognized.

readlines(*hint=-1*, */*)

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

hint values of `0` or less, as well as `None`, are treated as no hint.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

seek(*offset*, *whence=os.SEEK_SET*, */*)

Change the stream position to the given byte *offset*, interpreted relative to the position indicated by *whence*, and return the new absolute position. Values for *whence* are:

- *os.SEEK_SET* or `0` – start of the stream (the default); *offset* should be zero or positive
- *os.SEEK_CUR* or `1` – current stream position; *offset* may be negative
- *os.SEEK_END* or `2` – end of the stream; *offset* is usually negative

Added in version 3.1: The `SEEK_*` constants.

Added in version 3.3: Some operating systems could support additional values, like *os.SEEK_HOLE* or *os.SEEK_DATA*. The valid values for a file could depend on it being open in text or binary mode.

seekable()

Return `True` if the stream supports random access. If `False`, *seek()*, *tell()* and *truncate()* will raise *OSError*.

tell()

Return the current stream position.

truncate(*size=None*, */*)

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled). The new file size is returned.

Changed in version 3.5: Windows will now zero-fill files when extending.

writable()

Return `True` if the stream supports writing. If `False`, `write()` and *truncate()* will raise *OSError*.

writelines(*lines*, */*)

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

__del__()

Prepare for object destruction. *IOBase* provides a default implementation of this method that calls the instance's *close()* method.

class io.**RawIOBase**

Base class for raw binary streams. It inherits from *IOBase*.

Raw binary streams typically provide low-level access to an underlying OS device or API, and do not try to encapsulate it in high-level primitives (this functionality is done at a higher-level in buffered binary streams and text streams, described later in this page).

RawIOBase provides these methods in addition to those from *IOBase*:

read(*size=-1*, */*)

Read up to *size* bytes from the object and return them. As a convenience, if *size* is unspecified or -1, all bytes until EOF are returned. Otherwise, only one system call is ever made. Fewer than *size* bytes may be returned if the operating system call returns fewer than *size* bytes.

If 0 bytes are returned, and *size* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

The default implementation defers to *readall()* and *readinto()*.

readall()

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

readinto(*b*, */*)

Read bytes into a pre-allocated, writable *bytes-like object* *b*, and return the number of bytes read. For example, *b* might be a *bytearray*. If the object is in non-blocking mode and no bytes are available, `None` is returned.

write(*b*, */*)

Write the given *bytes-like object*, *b*, to the underlying raw stream, and return the number of bytes written. This can be less than the length of *b* in bytes, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. `None` is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

class io.**BufferedIOBase**

Base class for binary streams that support some kind of buffering. It inherits from *IOBase*.

The main difference with *RawIOBase* is that methods *read()*, *readinto()* and *write()* will try (respectively) to read as much input as requested or to emit all provided data.

In addition, if the underlying raw stream is in non-blocking mode, when the system returns would block *write()* will raise *BlockingIOError* with *BlockingIOError.characters_written* and *read()* will return data read so far or `None` if no data is available.

Besides, the *read()* method does not have a default implementation that defers to *readinto()*.

A typical *BufferedIOBase* implementation should not inherit from a *RawIOBase* implementation, but wrap one, like *BufferedWriter* and *BufferedReader* do.

BufferedIOBase provides or overrides these data attributes and methods in addition to those from *IOBase*:

raw

The underlying raw stream (a *RawIOBase* instance) that *BufferedIOBase* deals with. This is not part of the *BufferedIOBase* API and may not exist on some implementations.

detach()

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like *BytesIO*, do not have the concept of a single raw stream to return from this method. They raise *UnsupportedOperation*.

Added in version 3.1.

read(*size=-1*, /)

Read and return up to *size* bytes. If the argument is omitted, `None`, or negative read as much as possible.

Fewer bytes may be returned than requested. An empty *bytes* object is returned if the stream is already at EOF. More than one read may be made and calls may be retried if specific errors are encountered, see *os.read()* and **PEP 475** for more details. Less than size bytes being returned does not imply that EOF is imminent.

When reading as much as possible the default implementation will use `raw.readall` if available (which should implement *RawIOBase.readall()*), otherwise will read in a loop until read returns `None`, an empty *bytes*, or a non-retryable error. For most streams this is to EOF, but for non-blocking streams more data may become available.

> **Note**
>
> When the underlying raw stream is non-blocking, implementations may either raise *BlockingIOError* or return `None` if no data is available. *io* implementations return `None`.

read1(*size=-1*, /)

Read and return up to *size* bytes, calling *readinto()* which may retry if *EINTR* is encountered per **PEP 475**. If *size* is `-1` or not provided, the implementation will choose an arbitrary value for *size*.

> **Note**
>
> When the underlying raw stream is non-blocking, implementations may either raise *BlockingIOError* or return `None` if no data is available. *io* implementations return `None`.

readinto(*b*, /)

Read bytes into a pre-allocated, writable *bytes-like object* *b* and return the number of bytes read. For example, *b* might be a *bytearray*.

Like *read()*, multiple reads may be issued to the underlying raw stream, unless the latter is interactive.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

readinto1(*b*, /)

Read bytes into a pre-allocated, writable *bytes-like object* *b*, using at most one call to the underlying raw stream's *read()* (or *readinto()*) method. Return the number of bytes read.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

Added in version 3.5.

write(*b*, /)

Write the given *bytes-like object*, *b*, and return the number of bytes written (always equal to the length of *b* in bytes, since if the write fails an *OSError* will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a *BlockingIOError* is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

Raw File I/O

class io.**FileIO**(*name*, *mode='r'*, *closefd=True*, *opener=None*)

A raw binary stream representing an OS-level file containing bytes data. It inherits from *RawIOBase*.

The *name* can be one of two things:

- a character string or *bytes* object representing the path to the file which will be opened. In this case closefd must be `True` (the default) otherwise an error will be raised.
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access. When the FileIO object is closed this fd will be closed as well, unless *closefd* is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. *FileExistsError* will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The *read()* (when called with a positive argument), *readinto()* and *write()* methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing *os.open* as *opener* results in functionality similar to passing `None`).

The newly created file is *non-inheritable*.

See the *open()* built-in function for examples on using the *opener* parameter.

Changed in version 3.3: The *opener* parameter was added. The `'x'` mode was added.

Changed in version 3.4: The file is now non-inheritable.

FileIO provides these data attributes in addition to those from *RawIOBase* and *IOBase*:

mode

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class io.**BytesIO**(*initial_bytes=b''*)

A binary stream using an in-memory bytes buffer. It inherits from *BufferedIOBase*. The buffer is discarded when the *close()* method is called.

The optional argument *initial_bytes* is a *bytes-like object* that contains initial data.

BytesIO provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

getbuffer()

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

Note

As long as the view exists, the *BytesIO* object cannot be resized or closed.

Added in version 3.2.

getvalue()

Return *bytes* containing the entire contents of the buffer.

read1(*size=-1*, */*)

In *BytesIO*, this is the same as *read()*.

Changed in version 3.7: The *size* argument is now optional.

readinto1(*b*, */*)

In *BytesIO*, this is the same as *readinto()*.

Added in version 3.5.

class io.**BufferedReader**(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a readable, non seekable *RawIOBase* raw binary stream. It inherits from *BufferedIOBase*.

When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a *BufferedReader* for the given readable *raw* stream and *buffer_size*. If *buffer_size* is omitted, *DEFAULT_BUFFER_SIZE* is used.

BufferedReader provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

peek(*size=0*, */*)

Return bytes from the stream without advancing the position. The number of bytes returned may be less or more than requested. If the underlying raw stream is non-blocking and the operation would block, returns empty bytes.

read(*size=-1*, */*)

In *BufferedReader* this is the same as *io.BufferedIOBase.read()*

read1(*size=-1*, */*)

In *BufferedReader* this is the same as *io.BufferedIOBase.read1()*

Changed in version 3.7: The *size* argument is now optional.

class io.**BufferedWriter**(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a writeable, non seekable *RawIOBase* raw binary stream. It inherits from *BufferedIOBase*.

When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying *RawIOBase* object under various conditions, including:

- when the buffer gets too small for all pending data;
- when *flush()* is called;
- when a *seek()* is requested (for *BufferedRandom* objects);
- when the *BufferedWriter* object is closed or destroyed.

The constructor creates a *BufferedWriter* for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedWriter provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

flush()

Force bytes held in the buffer into the raw stream. A *BlockingIOError* should be raised if the raw stream blocks.

write(*b*, /)

Write the *bytes-like object*, *b*, and return the number of bytes written. When in non-blocking mode, a *BlockingIOError* with *BlockingIOError.characters_written* set is raised if the buffer needs to be written out but the raw stream blocks.

class io.**BufferedRandom**(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a seekable *RawIOBase* raw binary stream. It inherits from *BufferedReader* and *BufferedWriter*.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedRandom is capable of anything *BufferedReader* or *BufferedWriter* can do. In addition, *seek()* and *tell()* are guaranteed to be implemented.

class io.**BufferedRWPair**(*reader*, *writer*, *buffer_size=DEFAULT_BUFFER_SIZE*, /)

A buffered binary stream providing higher-level access to two non seekable *RawIOBase* raw binary streams—one readable, the other writeable. It inherits from *BufferedIOBase*.

reader and *writer* are *RawIOBase* objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedRWPair implements all of *BufferedIOBase*'s methods except for *detach()*, which raises *UnsupportedOperation*.

> **Warning**
>
> *BufferedRWPair* does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use *BufferedRandom* instead.

Text I/O

class io.**TextIOBase**

Base class for text streams. This class provides a character and line based interface to stream I/O. It inherits from *IOBase*.

TextIOBase provides or overrides these data attributes and methods in addition to those from *IOBase*:

encoding

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors

The error setting of the decoder or encoder.

newlines

A string, a tuple of strings, or `None`, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer

The underlying binary buffer (a *BufferedIOBase* or *RawIOBase* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist in some implementations.

detach()

Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

Added in version 3.1.

read(*size=-1*, /)

Read and return at most *size* characters from the stream as a single *str*. If *size* is negative or `None`, reads until EOF.

readline(*size=-1*, /)

Read until newline or EOF and return a single *str*. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

seek(*offset*, *whence=SEEK_SET*, /)

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is `SEEK_SET`.

- `SEEK_SET` or `0`: seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- `SEEK_CUR` or `1`: "seek" to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- `SEEK_END` or `2`: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

Added in version 3.1: The `SEEK_*` constants.

tell()

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(*s*, /)

Write the string *s* to the stream and return the number of characters written.

class io.**TextIOWrapper**(*buffer*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=False*, *write_through=False*)

A buffered text stream providing higher-level access to a *BufferedIOBase* buffered binary stream. It inherits from *TextIOBase*.

encoding gives the name of the encoding that the stream will be decoded or encoded with. In *UTF-8 Mode*, this defaults to UTF-8. Otherwise, it defaults to *locale.getencoding()*. `encoding="locale"` can be used to specify the current locale's encoding explicitly. See *Text Encoding* for more information.

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a *ValueError* exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. `'backslashreplace'` causes malformed data to be replaced by a backslashed escape sequence. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'namereplace'` (replace with `\N{...}` escape sequences) can be used. Any other error handling name that has been registered with *codecs.register_error()* is also valid.

newline controls how line endings are handled. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, *universal newlines* mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If *newline* is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If *newline* has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, *os.linesep*. If *newline* is `''` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *line_buffering* is `True`, *flush()* is implied when a call to write contains a newline character or a carriage return.

If *write_through* is `True`, calls to *write()* are guaranteed not to be buffered: any data written on the *TextIOWrapper* object is immediately handled to its underlying binary *buffer*.

Changed in version 3.3: The *write_through* argument has been added.

Changed in version 3.3: The default *encoding* is now `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. Don't change temporary the locale encoding using *locale.setlocale()*, use the current locale encoding instead of the user preferred encoding.

Changed in version 3.10: The *encoding* argument now supports the `"locale"` dummy encoding name.

TextIOWrapper provides these data attributes and methods in addition to those from *TextIOBase* and *IOBase*:

line_buffering

Whether line buffering is enabled.

write_through

Whether writes are passed immediately to the underlying binary buffer.

Added in version 3.7.

reconfigure(*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=None*, *write_through=None*)

Reconfigure this text stream using new settings for *encoding*, *errors*, *newline*, *line_buffering* and *write_through*.

Parameters not specified keep current settings, except `errors='strict'` is used when *encoding* is specified but *errors* is not specified.

It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

This method does an implicit stream flush before setting the new parameters.

Added in version 3.7.

Changed in version 3.11: The method supports `encoding="locale"` option.

seek(*cookie*, *whence=os.SEEK_SET*, **/**)

Set the stream position. Return the new stream position as an *int*.

Four operations are supported, given by the following argument combinations:

- `seek(0, SEEK_SET)`: Rewind to the start of the stream.
- `seek(cookie, SEEK_SET)`: Restore a previous position; *cookie* **must be** a number returned by *tell()*.
- `seek(0, SEEK_END)`: Fast-forward to the end of the stream.
- `seek(0, SEEK_CUR)`: Leave the current stream position unchanged.

Any other argument combinations are invalid, and may raise exceptions.

See also

os.SEEK_SET, *os.SEEK_CUR*, and *os.SEEK_END*.

tell()

Return the stream position as an opaque number. The return value of `tell()` can be given as input to *seek()*, to restore a previous stream position.

class io.**StringIO**(*initial_value=''*, *newline='\n'*)

A text stream using an in-memory text buffer. It inherits from *TextIOBase*.

The text buffer is discarded when the *close()* method is called.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by *write()*. The stream is positioned at the start of the buffer which emulates opening an existing file in a `w+` mode, making it ready for an immediate write from the beginning or for a write that would overwrite the initial value. To emulate opening a file in an `a+` mode ready for appending, use `f.seek(0, io.SEEK_END)` to reposition the stream at the end of the buffer.

The *newline* argument works like that of *TextIOWrapper*, except that when writing output to the stream, if *newline* is `None`, newlines are written as `\n` on all platforms.

StringIO provides this method in addition to those from *TextIOBase* and *IOBase*:

getvalue()

Return a *str* containing the entire contents of the buffer. Newlines are decoded as if by *read()*, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class io.**IncrementalNewlineDecoder**

A helper codec that decodes newlines for *universal newlines* mode. It inherits from *codecs.IncrementalDecoder*.

16.2.5 Performance

This section discusses the performance of the provided concrete I/O implementations.

Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, `tell()` and `seek()` are both quite slow due to the reconstruction algorithm used.

`StringIO`, however, is a native in-memory unicode container and will exhibit similar speed to `BytesIO`.

Multi-threading

`FileIO` objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they wrap are thread-safe too.

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

`TextIOWrapper` objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a `signal` handler. If a thread tries to re-enter a buffered object which it is already accessing, a `RuntimeError` is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the `open()` function will wrap a buffered object inside a `TextIOWrapper`. This includes standard streams and therefore affects the built-in `print()` function as well.

16.3 `time` — Time access and conversions

This module provides various time-related functions. For related functionality, see also the `datetime` and `calendar` modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts, the return value of `time.gmtime(0)`. It is January 1, 1970, 00:00:00 (UTC) on all platforms.
- The term *seconds since the epoch* refers to the total number of elapsed seconds since the epoch, typically excluding leap seconds. Leap seconds are excluded from this total on all POSIX-compliant platforms.
- The functions in this module may not handle dates and times before the *epoch* or far in the future. The cut-off point in the future is determined by the C library; for 32-bit systems, it is typically in 2038.

- Function *strptime()* can parse 2-digit years when given `%y` format code. When 2-digit years are parsed, they are converted according to the POSIX and ISO C standards: values 69–99 are mapped to 1969–1999, and values 0–68 are mapped to 2000–2068.
- UTC is Coordinated Universal Time and superseded Greenwich Mean Time or GMT as the basis of international timekeeping. The acronym UTC is not a mistake but conforms to an earlier, language-agnostic naming scheme for time standards such as UT0, UT1, and UT2.
- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.
- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock "ticks" only 50 or 100 times a second.
- On the other hand, the precision of *time()* and *sleep()* is better than their Unix equivalents: times are expressed as floating-point numbers, *time()* returns the most accurate time available (using Unix `gettimeofday()` where available), and *sleep()* will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- The time value as returned by *gmtime()*, *localtime()*, and *strptime()*, and accepted by *asctime()*, *mktime()* and *strftime()*, is a sequence of 9 integers. The return values of *gmtime()*, *localtime()*, and *strptime()* also offer attribute names for individual fields.

  See *struct_time* for a description of these objects.

  Changed in version 3.3: The *struct_time* type was extended to provide the *tm_gmtoff* and *tm_zone* attributes when platform supports corresponding `struct tm` members.

  Changed in version 3.6: The *struct_time* attributes *tm_gmtoff* and *tm_zone* are now available on all platforms.
- Use the following functions to convert between time representations:

From	To	Use
seconds since the epoch	*struct_time* in UTC	*gmtime()*
seconds since the epoch	*struct_time* in local time	*localtime()*
struct_time in UTC	seconds since the epoch	*calendar.timegm()*
struct_time in local time	seconds since the epoch	*mktime()*

16.3.1 Functions

`time.`**`asctime`**`(`[*t*]`)`

Convert a tuple or *struct_time* representing a time as returned by *gmtime()* or *localtime()* to a string of the following form: `'Sun Jun 20 23:21:05 1993'`. The day field is two characters long and is space padded if the day is a single digit, e.g.: `'Wed Jun 9 04:26:40 1993'`.

If *t* is not provided, the current time as returned by *localtime()* is used. Locale information is not used by *asctime()*.

> **Note**
>
> Unlike the C function of the same name, *asctime()* does not add a trailing newline.

`time.`**`pthread_getcpuclockid`**`(`*thread_id*`)`

Return the *clk_id* of the thread-specific CPU-time clock for the specified *thread_id*.

Use *threading.get_ident()* or the *ident* attribute of *threading.Thread* objects to get a suitable value for *thread_id*.

> **Warning**
>
> Passing an invalid or expired *thread_id* may result in undefined behavior, such as segmentation fault.

Availability: Unix

See the man page for `pthread_getcpuclockid(3)` for further information.

Added in version 3.7.

`time.`**`clock_getres`**(*clk_id*)

Return the resolution (precision) of the specified clock *clk_id*. Refer to *Clock ID Constants* for a list of accepted values for *clk_id*.

Availability: Unix.

Added in version 3.3.

`time.`**`clock_gettime`**(*clk_id*) → *float*

Return the time of the specified clock *clk_id*. Refer to *Clock ID Constants* for a list of accepted values for *clk_id*.

Use `clock_gettime_ns()` to avoid the precision loss caused by the `float` type.

Availability: Unix.

Added in version 3.3.

`time.`**`clock_gettime_ns`**(*clk_id*) → *int*

Similar to `clock_gettime()` but return time as nanoseconds.

Availability: Unix.

Added in version 3.7.

`time.`**`clock_settime`**(*clk_id*, *time:* float)

Set the time of the specified clock *clk_id*. Currently, `CLOCK_REALTIME` is the only accepted value for *clk_id*.

Use `clock_settime_ns()` to avoid the precision loss caused by the `float` type.

Availability: Unix, not Android, not iOS.

Added in version 3.3.

`time.`**`clock_settime_ns`**(*clk_id*, *time:* int)

Similar to `clock_settime()` but set time with nanoseconds.

Availability: Unix, not Android, not iOS.

Added in version 3.7.

`time.`**`ctime`**([*secs*])

Convert a time expressed in seconds since the *epoch* to a string of a form: `'Sun Jun 20 23:21:05 1993'` representing local time. The day field is two characters long and is space padded if the day is a single digit, e.g.: `'Wed Jun 9 04:26:40 1993'`.

If *secs* is not provided or `None`, the current time as returned by `time()` is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by `ctime()`.

`time.`**`get_clock_info`**(*name*)

Get information on the specified clock as a namespace object. Supported clock names and the corresponding functions to read their value are:

- `'monotonic'`: `time.monotonic()`
- `'perf_counter'`: `time.perf_counter()`
- `'process_time'`: `time.process_time()`

- `'thread_time'`: *time.thread_time()*
- `'time'`: *time.time()*

The result has the following attributes:

- *adjustable*: `True` if the clock can be changed automatically (e.g. by a NTP daemon) or manually by the system administrator, `False` otherwise
- *implementation*: The name of the underlying C function used to get the clock value. Refer to *Clock ID Constants* for possible values.
- *monotonic*: `True` if the clock cannot go backward, `False` otherwise
- *resolution*: The resolution of the clock in seconds (*float*)

Added in version 3.3.

time.**gmtime**([*secs*])

Convert a time expressed in seconds since the *epoch* to a *struct_time* in UTC in which the dst flag is always zero. If *secs* is not provided or *None*, the current time as returned by *time()* is used. Fractions of a second are ignored. See above for a description of the *struct_time* object. See *calendar.timegm()* for the inverse of this function.

time.**localtime**([*secs*])

Like *gmtime()* but converts to local time. If *secs* is not provided or *None*, the current time as returned by *time()* is used. The dst flag is set to `1` when DST applies to the given time.

localtime() may raise *OverflowError*, if the timestamp is outside the range of values supported by the platform C `localtime()` or `gmtime()` functions, and *OSError* on `localtime()` or `gmtime()` failure. It's common for this to be restricted to years between 1970 and 2038.

time.**mktime**(*t*)

This is the inverse function of *localtime()*. Its argument is the *struct_time* or full 9-tuple (since the dst flag is needed; use `-1` as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating-point number, for compatibility with *time()*. If the input value cannot be represented as a valid time, either *OverflowError* or *ValueError* will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

time.**monotonic**() → *float*

Return the value (in fractional seconds) of a monotonic clock, i.e. a clock that cannot go backwards. The clock is not affected by system clock updates. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Clock:

- On Windows, call `QueryPerformanceCounter()` and `QueryPerformanceFrequency()`.
- On macOS, call `mach_absolute_time()` and `mach_timebase_info()`.
- On HP-UX, call `gethrtime()`.
- Call `clock_gettime(CLOCK_HIGHRES)` if available.
- Otherwise, call `clock_gettime(CLOCK_MONOTONIC)`.

Use *monotonic_ns()* to avoid the precision loss caused by the *float* type.

Added in version 3.3.

Changed in version 3.5: The function is now always available and always system-wide.

Changed in version 3.10: On macOS, the function is now system-wide.

time.**monotonic_ns**() → *int*

Similar to *monotonic()*, but return time as nanoseconds.

Added in version 3.7.

time.**perf_counter**() → *float*

Return the value (in fractional seconds) of a performance counter, i.e. a clock with the highest available resolution to measure a short duration. It does include time elapsed during sleep and is system-wide. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

CPython implementation detail: On CPython, use the same clock as *time.monotonic()* and is a monotonic clock, i.e. a clock that cannot go backwards.

Use *perf_counter_ns()* to avoid the precision loss caused by the *float* type.

Added in version 3.3.

Changed in version 3.10: On Windows, the function is now system-wide.

Changed in version 3.13: Use the same clock as *time.monotonic()*.

time.**perf_counter_ns**() → *int*

Similar to *perf_counter()*, but return time as nanoseconds.

Added in version 3.7.

time.**process_time**() → *float*

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current process. It does not include time elapsed during sleep. It is process-wide by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use *process_time_ns()* to avoid the precision loss caused by the *float* type.

Added in version 3.3.

time.**process_time_ns**() → *int*

Similar to *process_time()* but return time as nanoseconds.

Added in version 3.7.

time.**sleep**(*secs*)

Suspend execution of the calling thread for the given number of seconds. The argument may be a floating-point number to indicate a more precise sleep time.

If the sleep is interrupted by a signal and no exception is raised by the signal handler, the sleep is restarted with a recomputed timeout.

The suspension time may be longer than requested by an arbitrary amount, because of the scheduling of other activity in the system.

Windows implementation

On Windows, if *secs* is zero, the thread relinquishes the remainder of its time slice to any other thread that is ready to run. If there are no other threads ready to run, the function returns immediately, and the thread continues execution. On Windows 8.1 and newer the implementation uses a high-resolution timer which provides resolution of 100 nanoseconds. If *secs* is zero, `Sleep(0)` is used.

Unix implementation

- Use `clock_nanosleep()` if available (resolution: 1 nanosecond);
- Or use `nanosleep()` if available (resolution: 1 nanosecond);
- Or use `select()` (resolution: 1 microsecond).

Note

To emulate a "no-op", use `pass` instead of `time.sleep(0)`.

To voluntarily relinquish the CPU, specify a real-time *scheduling policy* and use `os.sched_yield()` instead.

Raises an *auditing event* `time.sleep` with argument `secs`.

Changed in version 3.5: The function now sleeps at least *secs* even if the sleep is interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale).

Changed in version 3.11: On Unix, the `clock_nanosleep()` and `nanosleep()` functions are now used if available. On Windows, a waitable timer is now used.

Changed in version 3.13: Raises an auditing event.

`time.`**`strftime`**(*format*[, *t*])

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by `localtime()` is used. *format* must be a string. `ValueError` is raised if any field in *t* is outside of the allowed range.

0 is a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the `strftime()` result:

Directive	Meaning	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%f	**Microseconds as a decimal number** [000000,999999].	(1)
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(2)
%S	Second as a decimal number [00,61].	(3)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(4)
%u	Day of the week (Monday is 1; Sunday is 7) as a decimal number [1, 7].	
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(4)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%z	Time zone offset indicating a positive or negative time difference from UTC/GMT of the form +HHMM or -HHMM, where H represents decimal hour digits and M represents decimal minute digits [-23:59, +23:59].[1]	
%Z	Time zone name (no characters	

Notes:

(1) The `%f` format directive only applies to *strptime()*, not to *strftime()*. However, see also *datetime.datetime.strptime()* and *datetime.datetime.strftime()* where the `%f` format directive *applies to microseconds*.

(2) When used with the *strptime()* function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.

(3) The range really is `0` to `61`; value `60` is valid in timestamps representing leap seconds and value `61` is supported for historical reasons.

(4) When used with the *strptime()* function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the **RFC 2822** Internet email standard.[1]

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the *strftime(3)* documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial `'%'` of a directive in the following order; this is also not portable. The field width is normally 2 except for `%j` where it is 3.

`time.`**`strptime`**(*string*[, *format*])

Parse a string representing a time according to a format. The return value is a *struct_time* as returned by *gmtime()* or *localtime()*.

The *format* parameter uses the same directives as those used by *strftime()*; it defaults to `"%a %b %d %H:%M:%S %Y"` which matches the formatting returned by *ctime()*. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, *ValueError* is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are `(1900, 1, 1, 0, 0, 0, 0, 1, -1)`. Both *string* and *format* must be strings.

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                 tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the `%Z` directive is based on the values contained in `tzname` and whether `daylight` is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because `strftime()` is implemented per platform it can sometimes offer more directives than those listed. But `strptime()` is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

`class` `time.`**`struct_time`**

The type of the time value sequence returned by *gmtime()*, *localtime()*, and *strptime()*. It is an object with a *named tuple* interface: values can be accessed by index and by attribute name. The following values are present:

[1] The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 **RFC 822** standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, **RFC 822** became obsolete and the 4-digit year has been first recommended by **RFC 1123** and then mandated by **RFC 2822**.

Index	Attribute	Values
0	**tm_year**	(for example, 1993)
1	**tm_mon**	range [1, 12]
2	**tm_mday**	range [1, 31]
3	**tm_hour**	range [0, 23]
4	**tm_min**	range [0, 59]
5	**tm_sec**	range [0, 61]; see *Note (2)* in *strftime()*
6	**tm_wday**	range [0, 6]; Monday is 0
7	**tm_yday**	range [1, 366]
8	**tm_isdst**	0, 1 or -1; see below
N/A	**tm_zone**	abbreviation of timezone name
N/A	**tm_gmtoff**	offset east of UTC in seconds

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11].

In calls to *mktime()*, *tm_isdst* may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a *struct_time*, or having elements of the wrong type, a *TypeError* is raised.

time.**time**() → *float*

Return the time in seconds since the *epoch* as a floating-point number. The handling of leap seconds is platform dependent. On Windows and most Unix systems, the leap seconds are not counted towards the time in seconds since the *epoch*. This is commonly referred to as Unix time.

Note that even though the time is always returned as a floating-point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

The number returned by *time()* may be converted into a more common time format (i.e. year, month, day, hour, etc…) in UTC by passing it to *gmtime()* function or in local time by passing it to the *localtime()* function. In both cases a *struct_time* object is returned, from which the components of the calendar date may be accessed as attributes.

Clock:

- On Windows, call `GetSystemTimeAsFileTime()`.

- Call `clock_gettime(CLOCK_REALTIME)` if available.
- Otherwise, call `gettimeofday()`.

Use *time_ns()* to avoid the precision loss caused by the *float* type.

`time.`**`time_ns`**`()` → *int*

Similar to *time()* but returns time as an integer number of nanoseconds since the *epoch*.

Added in version 3.7.

`time.`**`thread_time`**`()` → *float*

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current thread. It does not include time elapsed during sleep. It is thread-specific by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls in the same thread is valid.

Use *thread_time_ns()* to avoid the precision loss caused by the *float* type.

Availability: Linux, Unix, Windows.

Unix systems supporting `CLOCK_THREAD_CPUTIME_ID`.

Added in version 3.7.

`time.`**`thread_time_ns`**`()` → *int*

Similar to *thread_time()* but return time as nanoseconds.

Added in version 3.7.

`time.`**`tzset`**`()`

Reset the time conversion rules used by the library routines. The environment variable `TZ` specifies how this is done. It will also set the variables `tzname` (from the `TZ` environment variable), `timezone` (non-DST seconds West of UTC), `altzone` (DST seconds west of UTC) and `daylight` (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

Availability: Unix.

Note

Although in many cases, changing the `TZ` environment variable may affect the output of functions like *localtime()* without calling *tzset()*, this behavior should not be relied on.

The `TZ` environment variable should contain no whitespace.

The standard format of the `TZ` environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

Where the components are:

`std` and `dst`
: Three or more alphanumerics giving the timezone abbreviations. These will be propagated into time.tzname

`offset`
: The offset has the form: `± hh[:mm[:ss]]`. This indicates the value added the local time to arrive at UTC. If preceded by a '-', the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows dst, summer time is assumed to be one hour ahead of standard time.

`start[/time], end[/time]`
: Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

Jn
The Julian day *n* (1 <= *n* <= 365). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

n
The zero-based Julian day (0 <= *n* <= 365). Leap days are counted, and it is possible to refer to February 29.

Mm.n.d
The *d*'th day (0 <= *d* <= 6) of week *n* of month *m* of the year (1 <= *n* <= 5, 1 <= *m* <= 12, where week 5 means "the last *d* day in month *m*" which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*'th day occurs. Day zero is a Sunday.

`time` has the same format as `offset` except that no leading sign ('-' or '+') is allowed. The default, if time is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo (*tzfile(5)*) database to specify the timezone rules. To do this, set the `TZ` environment variable to the path of the required timezone datafile, relative to the root of the systems 'zoneinfo' timezone database, usually located at `/usr/share/zoneinfo`. For example, `'US/Eastern'`, `'Australia/Melbourne'`, `'Egypt'` or `'Europe/Amsterdam'`.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

16.3.2 Clock ID Constants

These constants are used as parameters for *clock_getres()* and *clock_gettime()*.

`time.`**CLOCK_BOOTTIME**
Identical to *CLOCK_MONOTONIC*, except it also includes any time that the system is suspended.

This allows applications to get a suspend-aware monotonic clock without having to deal with the complications of *CLOCK_REALTIME*, which may have discontinuities if the time is changed using `settimeofday()` or similar.

Availability: Linux >= 2.6.39.

Added in version 3.7.

`time.`**CLOCK_HIGHRES**
The Solaris OS has a `CLOCK_HIGHRES` timer that attempts to use an optimal hardware source, and may give close to nanosecond resolution. `CLOCK_HIGHRES` is the nonadjustable, high-resolution clock.

Availability: Solaris.

Added in version 3.3.

time.**CLOCK_MONOTONIC**

Clock that cannot be set and represents monotonic time since some unspecified starting point.

Availability: Unix.

Added in version 3.3.

time.**CLOCK_MONOTONIC_RAW**

Similar to *CLOCK_MONOTONIC*, but provides access to a raw hardware-based time that is not subject to NTP adjustments.

Availability: Linux >= 2.6.28, macOS >= 10.12.

Added in version 3.3.

time.**CLOCK_MONOTONIC_RAW_APPROX**

Similar to *CLOCK_MONOTONIC_RAW*, but reads a value cached by the system at context switch and hence has less accuracy.

Availability: macOS >= 10.12.

Added in version 3.13.

time.**CLOCK_PROCESS_CPUTIME_ID**

High-resolution per-process timer from the CPU.

Availability: Unix.

Added in version 3.3.

time.**CLOCK_PROF**

High-resolution per-process timer from the CPU.

Availability: FreeBSD, NetBSD >= 7, OpenBSD.

Added in version 3.7.

time.**CLOCK_TAI**

International Atomic Time

The system must have a current leap second table in order for this to give the correct answer. PTP or NTP software can maintain a leap second table.

Availability: Linux.

Added in version 3.9.

time.**CLOCK_THREAD_CPUTIME_ID**

Thread-specific CPU-time clock.

Availability: Unix.

Added in version 3.3.

time.**CLOCK_UPTIME**

Time whose absolute value is the time the system has been running and not suspended, providing accurate uptime measurement, both absolute and interval.

Availability: FreeBSD, OpenBSD >= 5.5.

Added in version 3.7.

time.**CLOCK_UPTIME_RAW**

Clock that increments monotonically, tracking the time since an arbitrary point, unaffected by frequency or time adjustments and not incremented while the system is asleep.

Availability: macOS >= 10.12.

Added in version 3.8.

time.**CLOCK_UPTIME_RAW_APPROX**

Like *CLOCK_UPTIME_RAW*, but the value is cached by the system at context switches and therefore has less accuracy.

Availability: macOS >= 10.12.

Added in version 3.13.

The following constant is the only parameter that can be sent to *clock_settime()*.

time.**CLOCK_REALTIME**

System-wide real-time clock. Setting this clock requires appropriate privileges.

Availability: Unix.

Added in version 3.3.

16.3.3 Timezone Constants

time.**altzone**

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if `daylight` is nonzero. See note below.

time.**daylight**

Nonzero if a DST timezone is defined. See note below.

time.**timezone**

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK). See note below.

time.**tzname**

A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used. See note below.

Note

For the above Timezone constants (*altzone*, *daylight*, *timezone*, and *tzname*), the value is determined by the timezone rules in effect at module load time or the last time *tzset()* is called and may be incorrect for times in the past. It is recommended to use the *tm_gmtoff* and *tm_zone* results from *localtime()* to obtain timezone information.

See also

Module *datetime*
More object-oriented interface to dates and times.

Module *locale*
Internationalization services. The locale setting affects the interpretation of many format specifiers in *strftime()* and *strptime()*.

Module *calendar*
General calendar-related functions. *timegm()* is the inverse of *gmtime()* from this module.

16.4 `logging` — Logging facility for Python

Source code: Lib/logging/__init__.py

Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

Here's a simple example of idiomatic usage:

```
# myapp.py
import logging
import mylib
logger = logging.getLogger(__name__)

def main():
    logging.basicConfig(filename='myapp.log', level=logging.INFO)
    logger.info('Started')
    mylib.do_something()
    logger.info('Finished')

if __name__ == '__main__':
    main()
```

```
# mylib.py
import logging
logger = logging.getLogger(__name__)

def do_something():
    logger.info('Doing something')
```

If you run *myapp.py*, you should see this in *myapp.log*:

```
INFO:__main__:Started
INFO:mylib:Doing something
INFO:__main__:Finished
```

The key feature of this idiomatic usage is that the majority of code is simply creating a module level logger with `getLogger(__name__)`, and using that logger to do any needed logging. This is concise, while allowing downstream code fine-grained control if needed. Logged messages to the module-level logger get forwarded to handlers of loggers in higher-level modules, all the way up to the highest-level logger known as the root logger; this approach is known as hierarchical logging.

For logging to be useful, it needs to be configured: setting the levels and destinations for each logger, potentially changing how specific modules log, often based on command-line arguments or application configuration. In most cases, like the one above, only the root logger needs to be so configured, since all the lower level loggers at module level eventually forward their messages to its handlers. *basicConfig()* provides a quick way to configure the root logger that handles many use cases.

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to view the tutorials (**see the links above and on the right**).

The basic classes defined by the module, together with their attributes and methods, are listed in the sections below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

16.4.1 Logger Objects

Loggers have the following attributes and methods. Note that Loggers should *NEVER* be instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to *getLogger()* with the same name will always return a reference to the same Logger object.

The `name` is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. In addition, all loggers are descendants of the root logger. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

class logging.**Logger**

name

This is the logger's name, and is the value that was passed to *getLogger()* to obtain the logger.

> **Note**
>
> This attribute should be treated as read-only.

level

The threshold of this logger, as set by the *setLevel()* method.

> **Note**
>
> Do not set this attribute directly - always use *setLevel()*, which has checks for the level passed to it.

parent

The parent logger of this logger. It may change based on later instantiation of loggers which are higher up in the namespace hierarchy.

> **Note**
>
> This value should be treated as read-only.

propagate

If this attribute evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

Spelling it out with an example: If the propagate attribute of the logger named `A.B.C` evaluates to true, any event logged to `A.B.C` via a method call such as `logging.getLogger('A.B.C').error(...)` will [subject to passing that logger's level and filter settings] be passed in turn to any handlers attached to loggers named `A.B`, `A` and the root logger, after first being passed to any handlers attached to `A.B.C`. If any logger in the chain `A.B.C`, `A.B`, `A` has its `propagate` attribute set to false, then that is the last logger whose handlers are offered the event to handle, and propagation stops at that point.

The constructor sets this attribute to `True`.

> **Note**
>
> If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

handlers

The list of handlers directly attached to this logger instance.

> **Note**
>
> This attribute should be treated as read-only; it is normally changed via the *addHandler()* and *removeHandler()* methods, which use locks to ensure thread-safe operation.

disabled

This attribute disables handling of any events. It is set to `False` in the initializer, and only changed by logging configuration code.

> **Note**
>
> This attribute should be treated as read-only.

setLevel(*level*)

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

When a logger is created, the level is set to *NOTSET* (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level *WARNING*.

The term 'delegation to the parent' means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

If an ancestor is found with a level other than NOTSET, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

See *Logging Levels* for a list of levels.

Changed in version 3.2: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as *INFO*. Note, however, that levels are internally

stored as integers, and methods such as e.g. *getEffectiveLevel()* and *isEnabledFor()* will return/expect to be passed integers.

isEnabledFor(*level*)

Indicates if a message of severity *level* would be processed by this logger. This method checks first the module-level level set by `logging.disable(level)` and then the logger's effective level as determined by *getEffectiveLevel()*.

getEffectiveLevel()

Indicates the effective level for this logger. If a value other than *NOTSET* has been set using *setLevel()*, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than *NOTSET* is found, and that value is returned. The value returned is an integer, typically one of *logging.DEBUG*, *logging.INFO* etc.

getChild(*suffix*)

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

Added in version 3.2.

getChildren()

Returns a set of loggers which are immediate children of this logger. So for example `logging.getLogger().getChildren()` might return a set containing loggers named `foo` and `bar`, but a logger named `foo.bar` wouldn't be included in the set. Likewise, `logging.getLogger('foo').getChildren()` might return a set including a logger named `foo.bar`, but it wouldn't include one named `foo.bar.baz`.

Added in version 3.12.

debug(*msg*, **args*, ***kwargs*)

Logs a message with level *DEBUG* on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.) No % formatting operation is performed on *msg* when no *args* are supplied.

There are four keyword arguments in *kwargs* which are inspected: *exc_info*, *stack_info*, *stacklevel* and *extra*.

If *exc_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by *sys.exc_info()*) or an exception instance is provided, it is used; otherwise, *sys.exc_info()* is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *stacklevel*, which defaults to `1`. If greater than 1, the corresponding number of stack frames are skipped when computing the line number and function name set in the *LogRecord* created for the logging event. This can be used in logging helpers so that the function name,

filename and line number recorded are not the information for the helper function/method, but rather its caller. The name of this parameter mirrors the equivalent one in the *warnings* module.

The fourth keyword argument is *extra* which can be used to pass a dictionary which is used to populate the __dict__ of the *LogRecord* created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protocol problem: connection␣
↪reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the section on *LogRecord attributes* for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the *LogRecord*. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatter*s would be used with particular *Handler*s.

If no handler is attached to this logger (or any of its ancestors, taking into account the relevant *Logger.propagate* attributes), the message will be sent to the handler set on *lastResort*.

Changed in version 3.2: The *stack_info* parameter was added.

Changed in version 3.5: The *exc_info* parameter can now accept exception instances.

Changed in version 3.8: The *stacklevel* parameter was added.

info(*msg*, **args*, ***kwargs*)

Logs a message with level *INFO* on this logger. The arguments are interpreted as for *debug()*.

warning(*msg*, **args*, ***kwargs*)

Logs a message with level *WARNING* on this logger. The arguments are interpreted as for *debug()*.

> **Note**
>
> There is an obsolete method `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

error(*msg*, **args*, ***kwargs*)

Logs a message with level *ERROR* on this logger. The arguments are interpreted as for *debug()*.

critical(*msg*, **args*, ***kwargs*)

Logs a message with level *CRITICAL* on this logger. The arguments are interpreted as for *debug()*.

log(*level*, *msg*, **args*, ***kwargs*)

Logs a message with integer level *level* on this logger. The other arguments are interpreted as for *debug()*.

exception(*msg*, **args*, ***kwargs*)

Logs a message with level *ERROR* on this logger. The arguments are interpreted as for *debug()*. Exception info is added to the logging message. This method should only be called from an exception handler.

addFilter(*filter*)

Adds the specified filter *filter* to this logger.

removeFilter(*filter*)

Removes the specified filter *filter* from this logger.

filter(*record*)

Apply this logger's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

addHandler(*hdlr*)

Adds the specified handler *hdlr* to this logger.

removeHandler(*hdlr*)

Removes the specified handler *hdlr* from this logger.

findCaller(*stack_info=False*, *stacklevel=1*)

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack_info* is `True`.

The *stacklevel* parameter is passed from code calling the *debug()* and other APIs. If greater than 1, the excess is used to skip stack frames before determining the values to be returned. This will generally be useful when calling logging APIs from helper/wrapper code, so that the information in the event log refers not to the helper/wrapper code, but to the code that calls it.

handle(*record*)

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using *filter()*.

makeRecord(*name*, *level*, *fn*, *lno*, *msg*, *args*, *exc_info*, *func=None*, *extra=None*, *sinfo=None*)

This is a factory method which can be overridden in subclasses to create specialized *LogRecord* instances.

hasHandlers()

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the 'propagate' attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

Added in version 3.2.

Changed in version 3.7: Loggers can now be pickled and unpickled.

16.4.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

Level	Numeric value	What it means / When to use it
`logging.NOTSET`	0	When set on a logger, indicates that ancestor loggers are to be consulted to determine the effective level. If that still resolves to `NOTSET`, then all events are logged. When set on a handler, all events are handled.
`logging.DEBUG`	10	Detailed information, typically only of interest to a developer trying to diagnose a problem.
`logging.INFO`	20	Confirmation that things are working as expected.
`logging.WARNING`	30	An indication that something unexpected happened, or that a problem might occur in the near future (e.g. 'disk space low'). The software is still working as expected.
`logging.ERROR`	40	Due to a more serious problem, the software has not been able to perform some function.
`logging.CRITICAL`	50	A serious error, indicating that the program itself may be unable to continue running.

16.4.3 Handler Objects

Handlers have the following attributes and methods. Note that *Handler* is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *Handler.__init__()*.

class logging.**Handler**

__init__(*level=NOTSET*)

Initializes the *Handler* instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

createLock()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

acquire()

Acquires the thread lock created with *createLock()*.

release()

Releases the thread lock acquired with *acquire()*.

setLevel(*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to *NOTSET* (which causes all messages to be processed).

See *Logging Levels* for a list of levels.

Changed in version 3.2: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as *INFO*.

setFormatter(*fmt*)

Sets the formatter for this handler to *fmt*. The *fmt* argument must be a *Formatter* instance or `None`.

addFilter(*filter*)

Adds the specified filter *filter* to this handler.

removeFilter(*filter*)

Removes the specified filter *filter* from this handler.

filter(*record*)

Apply this handler's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

flush()

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

close()

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal map of handlers, which is used for handler lookup by name.

Subclasses should ensure that this gets called from overridden *close()* methods.

handle(*record*)

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

handleError(*record*)

This method should be called from handlers when an exception is encountered during an *emit()* call. If the module-level attribute *raiseExceptions* is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of *raiseExceptions* is `True`, as that is more useful during development).

format(*record*)

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

emit(*record*)

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a *NotImplementedError*.

> **Warning**
>
> This method is called after a handler-level lock is acquired, which is released after this method returns. When you override this method, note that you should be careful when calling anything that invokes other parts of the logging API which might do locking, because that might result in a deadlock. Specifically:
>
> - Logging configuration APIs acquire the module-level lock, and then individual handler-level locks as those handlers are configured.
> - Many logging APIs lock the module-level lock. If such an API is called from this method, it could cause a deadlock if a configuration call is made on another thread, because that thread will try to acquire the module-level lock *before* the handler-level lock, whereas this thread tries to acquire the module-level lock *after* the handler-level lock (because in this method, the handler-level lock has already been acquired).

For a list of handlers included as standard, see *logging.handlers*.

16.4.4 Formatter Objects

class logging.**Formatter**(*fmt=None*, *datefmt=None*, *style='%'*, *validate=True*, *, *defaults=None*)

Responsible for converting a *LogRecord* to an output string to be interpreted by a human or external system.

Parameters

- **fmt** (str) – A format string in the given *style* for the logged output as a whole. The possible mapping keys are drawn from the *LogRecord* object's *LogRecord attributes*. If not specified, '%(message)s' is used, which is just the logged message.
- **datefmt** (str) – A format string in the given *style* for the date/time portion of the logged output. If not specified, the default described in *formatTime()* is used.
- **style** (str) – Can be one of '%', '{' or '$' and determines how the format string will be merged with its data: using one of *printf-style String Formatting* (%), *str.format()* ({) or *string.Template* ($). This only applies to *fmt* and *datefmt* (e.g. '%(message)s' versus '{message}'), not to the actual log messages passed to the logging methods. However, there are other ways to use {- and $-formatting for log messages.
- **validate** (bool) – If True (the default), incorrect or mismatched *fmt* and *style* will raise a *ValueError*; for example, logging.Formatter('%(asctime)s - %(message)s', style='{').
- **defaults** (dict[str, Any]) – A dictionary with default values to use in custom fields. For example, logging.Formatter('%(ip)s %(message)s', defaults={"ip": None})

Changed in version 3.2: Added the *style* parameter.

Changed in version 3.8: Added the *validate* parameter.

Changed in version 3.10: Added the *defaults* parameter.

format(*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The *message* attribute of the record is computed using *msg % args*. If the formatting string contains '(asctime)', *formatTime()* is called to format the event time. If there is exception information, it is formatted using *formatException()* and appended to the message. Note that the formatted exception information is cached in attribute *exc_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one *Formatter* subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value (by setting the *exc_text* attribute to None) after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value, but recalculates it afresh.

If stack information is available, it's appended after the exception information, using *formatStack()* to transform it if necessary.

formatTime(*record*, *datefmt=None*)

This method should be called from *format()* by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the format '%Y-%m-%d %H:%M:%S,uuu' is used, where the uuu part is a millisecond value and the other letters are as per the *time.strftime()* documentation. An example time in this format is 2003-01-23 00:29:50,411. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used; to change this for a particular formatter instance, set the converter attribute to a function with the same signature as *time.localtime()* or *time.gmtime()*. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the converter attribute in the Formatter class.

Changed in version 3.3: Previously, the default format was hard-coded as in this example: 2010-09-06 22:38:15,292 where the part before the comma is handled by a strptime format string ('%Y-%m-%d

`%H:%M:%S`'), and the part after the comma is a millisecond value. Because strptime does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, `'%s,%03d'` — and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are `default_time_format` (for the strptime format string) and `default_msec_format` (for appending the millisecond value).

Changed in version 3.9: The `default_msec_format` can be `None`.

formatException(*exc_info*)

Formats the specified exception information (a standard exception tuple as returned by *sys.exc_info()*) as a string. This default implementation just uses *traceback.print_exception()*. The resulting string is returned.

formatStack(*stack_info*)

Formats the specified stack information (a string as returned by *traceback.print_stack()*, but with the last newline removed) as a string. This default implementation just returns the input value.

class logging.**BufferingFormatter**(*linefmt=None*)

A base formatter class suitable for subclassing when you want to format a number of records. You can pass a *Formatter* instance which you want to use to format each line (that corresponds to a single record). If not specified, the default formatter (which just outputs the event message) is used as the line formatter.

formatHeader(*records*)

Return a header for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records, a title or a separator line.

formatFooter(*records*)

Return a footer for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records or a separator line.

format(*records*)

Return formatted text for a list of *records*. The base implementation just returns the empty string if there are no records; otherwise, it returns the concatenation of the header, each record formatted with the line formatter, and the footer.

16.4.5 Filter Objects

`Filters` can be used by `Handlers` and `Loggers` for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all events are passed.

class logging.**Filter**(*name=''*)

Returns an instance of the *Filter* class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter(*record*)

Is the specified record to be logged? Returns false for no, true for yes. Filters can either modify log records in-place or return a completely different record instance which will replace the original log record in any future processing of the event.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using *debug()*, *info()*, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

Changed in version 3.2: You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its *`filter()`* method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by *`filter()`*.

Changed in version 3.12: You can now return a *`LogRecord`* instance from filters to replace the log record rather than modifying it in place. This allows filters attached to a *`Handler`* to modify the log record before it is emitted, without having side effects on other handlers.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the *`LogRecord`* being processed. Obviously changing the LogRecord needs to be done with some care, but it does allow the injection of contextual information into logs (see filters-contextual).

16.4.6 LogRecord Objects

`LogRecord` instances are created automatically by the *`Logger`* every time something is logged, and can be created manually via *`makeLogRecord()`* (for example, from a pickled event received over the wire).

class `logging.`**LogRecord**(*name*, *level*, *pathname*, *lineno*, *msg*, *args*, *exc_info*, *func=None*, *sinfo=None*)

Contains all the information pertinent to the event being logged.

The primary information is passed in *msg* and *args*, which are combined using `msg % args` to create the `message` attribute of the record.

Parameters

- **name** (`str`) – The name of the logger used to log the event represented by this `LogRecord`. Note that the logger name in the `LogRecord` will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** (`int`) – The *numeric level* of the logging event (such as `10` for `DEBUG`, `20` for `INFO`, etc). Note that this is converted to *two* attributes of the LogRecord: `levelno` for the numeric value and `levelname` for the corresponding level name.
- **pathname** (`str`) – The full string path of the source file where the logging call was made.
- **lineno** (`int`) – The line number in the source file where the logging call was made.
- **msg** (`Any`) – The event description message, which can be a %-format string with placeholders for variable data, or an arbitrary object (see arbitrary-object-messages).
- **args** (`tuple | dict[str, Any]`) – Variable data to merge into the *msg* argument to obtain the event description.
- **exc_info** (`tuple[type[BaseException], BaseException, types.TracebackType] | None`) – An exception tuple with the current exception information, as returned by *`sys.exc_info()`*, or `None` if no exception information is available.
- **func** (`str | None`) – The name of the function or method from which the logging call was invoked.
- **sinfo** (`str | None`) – A text string representing stack information from the base of the stack in the current thread, up to the logging call.

getMessage()

Returns the message for this *`LogRecord`* instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, *`str()`* is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

Changed in version 3.2: The creation of a *LogRecord* has been made more configurable by providing a factory which is used to create the record. The factory can be set using *getLogRecordFactory()* and *setLogRecordFactory()* (see this for the factory's signature).

This functionality can be used to inject your own values into a *LogRecord* at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

16.4.7 LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (*str.format()*), you can use `{attrname}` as the placeholder in the format string. If you are using $-formatting (*string.Template*), use the form `${attrname}`. In both cases, of course, replace `attrname` with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of `{msecs:03.0f}` would format a millisecond value of `4` as `004`. Refer to the *str.format()* documentation for full details on the options available to you.

Attribute name	Format	Description
args	You shouldn't need to format this yourself.	The tuple of arguments merged into `msg` to produce `message`, or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
asctime	`%(asctime)s`	Human-readable time when the *LogRecord* was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time).
created	`%(created)f`	Time when the *LogRecord* was created (as returned by *time.time_ns()* / 1e9).
exc_info	You shouldn't need to format this yourself.	Exception tuple (à la `sys.exc_info`) or, if no exception has occurred, `None`.
filename	`%(filename)s`	Filename portion of `pathname`.
funcName	`%(funcName)s`	Name of function containing the logging call.
levelname	`%(levelname)s`	Text logging level for the message (`'DEBUG'`, `'INFO'`, `'WARNING'`, `'ERROR'`, `'CRITICAL'`).
levelno	`%(levelno)s`	Numeric logging level for the message (*DEBUG*, *INFO*, *WARNING*, *ERROR*, *CRITICAL*).
lineno	`%(lineno)d`	Source line number where the logging call was issued (if available).
message	`%(message)s`	The logged message, computed as `msg % args`. This is set when *Formatter.format()* is invoked.
module	`%(module)s`	Module (name portion of `filename`).
msecs	`%(msecs)d`	Millisecond portion of the time when the *LogRecord* was created.
msg	You shouldn't need to format this yourself.	The format string passed in the original logging call. Merged with `args` to produce `message`, or an arbitrary object (see arbitrary-object-messages).
name	`%(name)s`	Name of the logger used to log the call.
pathname	`%(pathname)s`	Full pathname of the source file where the logging call was issued (if available).
process	`%(process)d`	Process ID (if available).
processName	`%(processName)s`	Process name (if available).
relativeCreated	`%(relativeCreated)d`	Time in milliseconds when the LogRecord was created, relative to the time the logging module was loaded.
stack_info	You shouldn't need to format this yourself.	Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record.
thread	`%(thread)d`	Thread ID (if available).
threadName	`%(threadName)s`	Thread name (if available).
taskName	`%(taskName)s`	*asyncio.Task* name (if available).

Changed in version 3.1: *processName* was added.

Changed in version 3.12: *taskName* was added.

16.4.8 LoggerAdapter Objects

LoggerAdapter instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

class logging.**LoggerAdapter**(*logger*, *extra*, *merge_extra=False*)

Returns an instance of *LoggerAdapter* initialized with an underlying *Logger* instance, a dict-like object (*extra*), and a boolean (*merge_extra*) indicating whether or not the *extra* argument of individual log calls should be merged with the *LoggerAdapter* extra. The default behavior is to ignore the *extra* argument of individual log calls and only use the one of the *LoggerAdapter* instance

process(*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

manager

Delegates to the underlying `manager` on *logger*.

_log

Delegates to the underlying `_log()` method on *logger*.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger*: *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()*, *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably.

Changed in version 3.2: The *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()* methods were added to *LoggerAdapter*. These methods delegate to the underlying logger.

Changed in version 3.6: Attribute `manager` and method `_log()` were added, which delegate to the underlying logger and allow adapters to be nested.

Changed in version 3.13: The *merge_extra* argument was added.

16.4.9 Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

16.4.10 Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

logging.**getLogger**(*name=None*)

Return a logger with the specified name or, if name is `None`, return the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like *'a'*, *'a.b'* or *'a.b.c.d'*. Choice of these names is entirely up to the developer who is using logging, though it is recommended that `__name__` be used unless you have a specific reason for not doing that, as mentioned in *Logger Objects*.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

logging.**getLoggerClass**()

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

logging.**getLogRecordFactory**()

Return a callable which is used to create a *LogRecord*.

Added in version 3.2: This function has been provided, along with *setLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

See *setLogRecordFactory()* for more information about the how the factory is called.

logging.**debug**(*msg*, **args*, ***kwargs*)

This is a convenience function that calls *Logger.debug()*, on the root logger. The handling of the arguments is in every way identical to what is described in that method.

The only difference is that if the root logger has no handlers, then *basicConfig()* is called, prior to calling `debug` on the root logger.

For very short scripts or quick demonstrations of `logging` facilities, `debug` and the other module-level functions may be convenient. However, most programs will want to carefully and explicitly control the logging configuration, and should therefore prefer creating a module-level logger and calling *Logger.debug()* (or other level-specific methods) on it, as described at the beginnning of this documentation.

logging.**info**(*msg*, **args*, ***kwargs*)

Logs a message with level *INFO* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**warning**(*msg*, **args*, ***kwargs*)

Logs a message with level *WARNING* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

> **Note**
>
> There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

logging.**error**(*msg*, **args*, ***kwargs*)

Logs a message with level *ERROR* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**critical**(*msg*, **args*, ***kwargs*)

Logs a message with level *CRITICAL* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**exception**(*msg*, **args*, ***kwargs*)

Logs a message with level *ERROR* on the root logger. The arguments and behavior are otherwise the same as for *debug()*. Exception info is added to the logging message. This function should only be called from an exception handler.

logging.**log**(*level*, *msg*, **args*, ***kwargs*)

Logs a message with level *level* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**disable**(*level=CRITICAL*)

Provides an overriding level *level* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *level* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is

called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the *level* parameter, but will have to explicitly supply a suitable value.

Changed in version 3.7: The *level* parameter was defaulted to level `CRITICAL`. See bpo-28524 for more information about this change.

`logging.`**`addLevelName`**(*level*, *levelName*)

Associates level *level* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a *Formatter* formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

> **Note**
>
> If you are thinking of defining your own levels, please see the section on custom-levels.

`logging.`**`getLevelNamesMapping`**()

Returns a mapping from level names to their corresponding logging levels. For example, the string "CRITICAL" maps to *CRITICAL*. The returned mapping is copied from an internal mapping on each call to this function.

Added in version 3.11.

`logging.`**`getLevelName`**(*level*)

Returns the textual or numeric representation of logging level *level*.

If *level* is one of the predefined levels *CRITICAL*, *ERROR*, *WARNING*, *INFO* or *DEBUG* then you get the corresponding string. If you have associated levels with names using *addLevelName()* then the name you have associated with *level* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned.

The *level* parameter also accepts a string representation of the level such as 'INFO'. In such cases, this functions returns the corresponding numeric value of the level.

If no matching numeric or string value is passed in, the string 'Level %s' % level is returned.

> **Note**
>
> Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see *LogRecord attributes*), and vice versa.

Changed in version 3.4: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

`logging.`**`getHandlerByName`**(*name*)

Returns a handler with the specified *name*, or `None` if there is no handler with that name.

Added in version 3.12.

`logging.`**`getHandlerNames`**()

Returns an immutable set of all known handler names.

Added in version 3.12.

logging.**makeLogRecord**(*attrdict*)

Creates and returns a new *LogRecord* instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled *LogRecord* attribute dictionary, sent over a socket, and reconstituting it as a *LogRecord* instance at the receiving end.

logging.**basicConfig**(***kwargs*)

Does basic configuration for the logging system by creating a *StreamHandler* with a default *Formatter* and adding it to the root logger. The functions *debug()*, *info()*, *warning()*, *error()* and *critical()* will call *basicConfig()* automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured, unless the keyword argument *force* is set to `True`.

> **Note**
>
> This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

Format	Description
filename	Specifies that a *FileHandler* be created, using the specified filename, rather than a *StreamHandler*.
filemode	If *filename* is specified, open the file in this *mode*. Defaults to `'a'`.
format	Use the specified format string for the handler. Defaults to attributes `levelname`, `name` and `message` separated by colons.
datefmt	Use the specified date/time format, as accepted by *time.strftime()*.
style	If *format* is specified, use this style for the format string. One of `'%'`, `'{'` or `'$'` for *printf-style*, *str.format()* or *string.Template* respectively. Defaults to `'%'`.
level	Set the root logger level to the specified *level*.
stream	Use the specified stream to initialize the *StreamHandler*. Note that this argument is incompatible with *filename* - if both are present, a `ValueError` is raised.
handlers	If specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with *filename* or *stream* - if both are present, a `ValueError` is raised.
force	If this keyword argument is specified as true, any existing handlers attached to the root logger are removed and closed, before carrying out the configuration as specified by the other arguments.
encoding	If this keyword argument is specified along with *filename*, its value is used when the *FileHandler* is created, and thus used when opening the output file.
errors	If this keyword argument is specified along with *filename*, its value is used when the *FileHandler* is created, and thus used when opening the output file. If not specified, the value 'backslashreplace' is used. Note that if `None` is specified, it will be passed as such to *open()*, which means that it will be treated the same as passing 'errors'.

Changed in version 3.2: The *style* argument was added.

Changed in version 3.3: The *handlers* argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. *handlers* together with *stream* or *filename*, or *stream* together with *filename*).

Changed in version 3.8: The *force* argument was added.

Changed in version 3.9: The *encoding* and *errors* arguments were added.

logging.**shutdown**()

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

When the logging module is imported, it registers this function as an exit handler (see *atexit*), so normally there's no need to do that manually.

logging.**setLoggerClass**(*klass*)

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior. After this call, as at any other time, do not instantiate loggers directly using the subclass: continue to use the *logging.getLogger()* API to get your loggers.

logging.**setLogRecordFactory**(*factory*)

Set a callable which is used to create a *LogRecord*.

Parameters
factory – The factory callable to be used to instantiate a log record.

Added in version 3.2: This function has been provided, along with *getLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

The factory has the following signature:

`factory(name, level, fn, lno, msg, args, exc_info, func=None, sinfo=None, **kwargs)`

name
The logger name.

level
The logging level (numeric).

fn
The full pathname of the file where the logging call was made.

lno
The line number in the file where the logging call was made.

msg
The logging message.

args
The arguments for the logging message.

exc_info
An exception tuple, or `None`.

func
The name of the function or method which invoked the logging call.

sinfo
A stack traceback such as is provided by *traceback.print_stack()*, showing the call hierarchy.

kwargs
Additional keyword arguments.

16.4.11 Module-Level Attributes

logging.**lastResort**

A "handler of last resort" is available through this attribute. This is a *StreamHandler* writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that "no

handlers could be found for logger XYZ". If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

Added in version 3.2.

`logging.`**`raiseExceptions`**

Used to see if exceptions during handling should be propagated.

Default: `True`.

If *`raiseExceptions`* is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors.

16.4.12 Integration with the warnings module

The *`captureWarnings()`* function can be used to integrate *`logging`* with the *`warnings`* module.

`logging.`**`captureWarnings`**(*capture*)

This function is used to turn the capture of warnings by logging on and off.

If *capture* is `True`, warnings issued by the *`warnings`* module will be redirected to the logging system. Specifically, a warning will be formatted using *`warnings.formatwarning()`* and the resulting string logged to a logger named `'py.warnings'` with a severity of *`WARNING`*.

If *capture* is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

Configuration API for the logging module.

Module *`logging.handlers`*
Useful handlers included with the logging module.

PEP 282 - A Logging System
The proposal which described this feature for inclusion in the Python standard library.

Original Python logging package
This is the original source for the *`logging`* package. The version of the package available from this site is suitable for use with Python 1.5.2, 2.1.x and 2.2.x, which do not include the *`logging`* package in the standard library.

16.5 `logging.config` — Logging configuration

Source code: Lib/logging/config.py

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

This section describes the API for configuring the logging module.

16.5.1 Configuration functions

The following functions configure the logging module. They are located in the *logging.config* module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in *logging* itself) and defining handlers which are declared either in *logging* or *logging.handlers*.

logging.config.**dictConfig**(*config*)

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a *ValueError*, *TypeError*, *AttributeError* or *ImportError* with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The *logging.config* module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

dictConfig() calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then *dictConfig()* could be called exactly as in the default, uncustomized state.

Added in version 3.2.

logging.config.**fileConfig**(*fname*, *defaults=None*, *disable_existing_loggers=True*, *encoding=None*)

Reads the logging configuration from a *configparser*-format file. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

It will raise *FileNotFoundError* if the file doesn't exist and *RuntimeError* if the file is invalid or empty.

Parameters

- **fname** – A filename, or a file-like object, or an instance derived from *RawConfigParser*. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a *ConfigParser* is instantiated, and the configuration read by it from the object passed in `fname`. If that has a *readline()* method, it is assumed to be a file-like object and read using *read_file()*; otherwise, it is assumed to be a filename and passed to *read()*.
- **defaults** – Defaults to be passed to the `ConfigParser` can be specified in this argument.
- **disable_existing_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing non-root loggers unless they or their ancestors are explicitly named in the logging configuration.

- **encoding** – The encoding used to open file when *fname* is filename.

Changed in version 3.4: An instance of a subclass of *RawConfigParser* is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

Changed in version 3.10: Added the *encoding* parameter.

Changed in version 3.12: An exception will be thrown if the provided file doesn't exist or is invalid or empty.

`logging.config.`**`listen`**(*port=DEFAULT_LOGGING_CONFIG_PORT*, *verify=None*)

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by *dictConfig()* or *fileConfig()*. Returns a *Thread* instance on which you can call *start()* to start the server, and which you can *join()* when appropriate. To stop the server, call *stopListening()*.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

Note

Because portions of the configuration are passed through *eval()*, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls *listen()*. Specifically, if the process calling *listen()* runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's *listen()* socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used. To avoid the risk of this happening, use the `verify` argument to *listen()* to prevent unrecognised configurations from being applied.

Changed in version 3.4: The `verify` argument was added.

Note

If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use *dictConfig()* for configuration. This method allows you to specify `disable_existing_loggers` as `False` in the configuration you send.

`logging.config.`**`stopListening`**()

Stops the listening server which was created with a call to *listen()*. This is typically called before calling `join()` on the return value from *listen()*.

16.5.2 Security considerations

The logging configuration functionality tries to offer convenience, and in part this is done by offering the ability to convert text in configuration files into Python objects used in logging configuration - for example, as described in *User-defined objects*. However, these same mechanisms (importing callables from user-defined modules and calling them with parameters from the configuration) could be used to invoke any code you like, and for this reason you should treat configuration files from untrusted sources with *extreme caution* and satisfy yourself that nothing bad can happen if you load them, before actually loading them.

16.5.3 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special `'()'` key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding `Formatter` instance.

  The configuring dict is searched for the following optional keys which correspond to the arguments passed to create a `Formatter` object:

  - `format`
  - `datefmt`
  - `style`
  - `validate` (since version >=3.8)
  - `defaults` (since version >=3.12)

  An optional `class` key indicates the name of the formatter's class (as a dotted module and class name). The instantiation arguments are as for `Formatter`, thus this key is most useful for instantiating a customised subclass of `Formatter`. For example, the alternative class might present exception tracebacks in an expanded or condensed format. If your formatter requires different or extra configuration keys, you should use *User-defined objects*.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

  The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a `logging.Filter` instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

  The configuring dict is searched for the following keys:

  - `class` (mandatory). This is the fully qualified name of the handler class.
  - `level` (optional). The level of the handler.
  - `formatter` (optional). The id of the formatter for this handler.

- `filters` (optional). A list of ids of the filters for this handler.

  Changed in version 3.11: `filters` can take filter instances in addition to ids.

All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level   : INFO
    filters: [allow_foo]
    stream  : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

the handler with id `console` is instantiated as a *`logging.StreamHandler`*, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a *`logging.handlers.RotatingFileHandler`* with the keyword arguments `filename='logconfig.log', maxBytes=1024, backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

  The configuring dict is searched for the following keys:

  - `level` (optional). The level of the logger.
  - `propagate` (optional). The propagation setting of the logger.
  - `filters` (optional). A list of ids of the filters for this logger.

    Changed in version 3.11: `filters` can take filter instances in addition to ids.

  - `handlers` (optional). A list of ids of the handlers for this logger.

  The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.

- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing *`fileConfig()`* API.

  If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.

- *disable_existing_loggers* - whether any existing non-root loggers are to be disabled. This setting mirrors the parameter of the same name in *`fileConfig()`*. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is

problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
   # configuration of handler with id 'h1' goes here
   formatter: brief
  h2: #This is another id
   # configuration of handler with id 'h2' goes here
   formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)
